NUCLEI MCU SOFTWARE INTERFACE STANDARD(NMSIS)

1.1 About NMSIS

The **NMSIS** is a vendor-independent hardware abstraction layer for micro-controllers that are based on [Nuclei Processors](#)¹.

The **NMSIS** defines generic tool interfaces and enables consistent device support. It provides simple software interfaces to the processor and the peripherals, simplifying software re-use, reducing the learning curve for micro-controller developers, and reducing the time to market for new devices.

1.2 NMSIS Components

NMSIS CORE All Nuclei N/NX Class Processors Standardized API for the Nuclei processor core and peripherals.

NMSIS DSP All Nuclei N/NX Class Processors DSP library collection with a lot of functions for various data types: fixed-point (fractional q7, q15, q31) and single precision floating-point (32-bit). Implementations optimized for the Nuclei Processors which has RISC-V SIMD instruction set.

NMSIS NN All Nuclei N/NX Class Processors Collection of efficient neural network kernels developed to maximize the performance and minimize the memory footprint Nuclei processor cores.

1.3 NMSIS Design

NMSIS is designed to help the Nuclei N/NX Class Processors processors in standardization. It enables consistent software layers and device support across a wide range of development tools and micro-controllers.

NMSIS is a lightweight software interface layer that tried to standardize common Nuclei processor-based SOC, and it didn't define any standard peripherals. The silicon industry can therefore support the wide variations of Nuclei processor-based devices with this common standard.

We can achieve the following benefits of **NMSIS**:

- **NMSIS** reduces the learning curve, development costs, and time-to-market. Developers can write software quicker through a variety of easy-to-use, standardized software interfaces.
- Consistent software interfaces improve the software portability and re-usability. Generic software libraries and interfaces provide consistent software framework.
- It provides interfaces for debug connectivity, debug peripheral views, software delivery, and device support to reduce time-to-market for new micro-controller deployment.

¹ https://doc.nucleisys.com/nuclei_spec

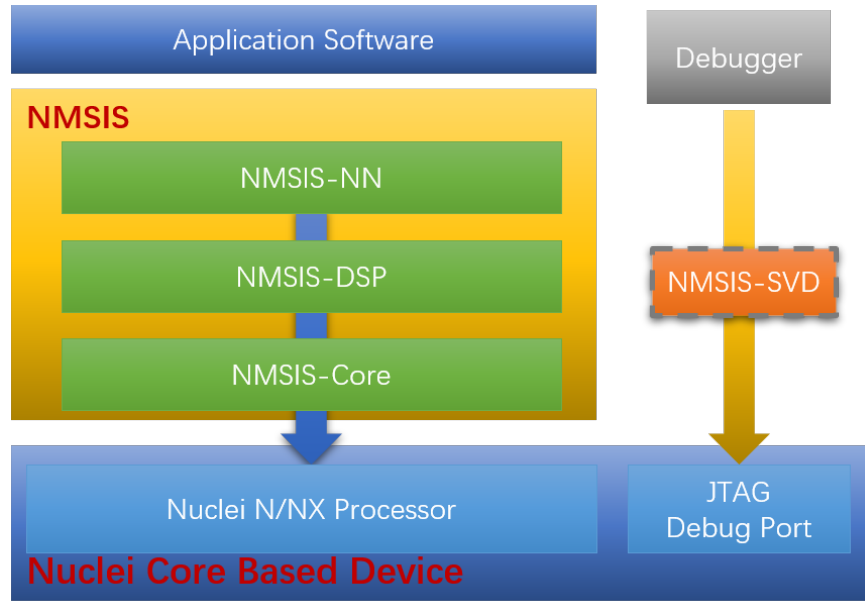

Fig. 1: NMSIS Design Diagram

- Being a compiler independent layer, it allows to use the compiler of your choice. Thus, it is supported by mainstream compilers.
- It enhances program debugging with peripheral information for debuggers.

1.4 How to Access

If you want to access the code of **NMSIS**, you can visit our opensource [NMSIS Github Repository](https://github.com/Nuclei-Software/NMSIS)².

1.5 Coding Rules

The **NMSIS** uses the following essential coding rules and conventions:

- Compliant with ANSI C (C99) and C++ (C++03).
- Uses ANSI C standard data types defined in **stdint.h**.
- Variables and parameters have a complete data type.
- Expressions for *#define* constants are enclosed in parenthesis.

In addition, the **NMSIS** recommends the following conventions for identifiers:

- **CAPITAL** names to identify Core Registers, Peripheral Registers, and CPU Instructions.
- **CamelCase** names to identify function names and interrupt functions.
- **Namespace_** prefixes avoid clashes with user identifiers and provide functional groups (i.e. for peripherals, RTOS, or DSP Library).

The **NMSIS** is documented within the source files with:

² <https://github.com/Nuclei-Software/NMSIS>

- Comments that use the C or C++ style.
- Doxygen compliant comments, which provide:
 - brief function, variable, macro overview.
 - detailed description of the function, variable, macro.
 - detailed parameter explanation.
 - detailed information about return values.

1.6 Validation

Nuclei uses RISC-V GCC Compiler in the various tests of **NMSIS**, and if more compiler is added, it could be easily supported by following the **NMSIS** compiler independent layer. For each component, the section **Validation** describes the scope of the various verifications.

NMSIS components are compatible with a range of C and C++ language standards.

As **NMSIS** defines API interfaces and functions that scale to a wide range of processors and devices, the scope of the run-time test coverage is limited. However, several components are validated using dedicated test suites.

1.7 License

This **NMSIS** is modified based on open-source project **CMSIS** to match Nuclei requirements.

This **NMSIS** is provided free of charge by Nuclei under the [Apache 2.0 License](http://www.apache.org/licenses/LICENSE-2.0)³.

NMSIS CORE

2.1 Overview

2.1.1 Introduction

NMSIS-Core implements the basic run-time system for a Nuclei N/NX Class Processors based device and gives the user access to the processor core and the device peripherals. In detail it defines:

- **Hardware Abstraction Layer (HAL)** for Nuclei processor registers with standardized definitions for the **CSR Registers, TIMER, ECLIC, PMP Registers, DSP Registers, FPU registers, and Core Access Functions**.
- **Standard core exception/interrupt names** to interface to system exceptions or interrupts without having compatibility issues.
- **Methods to organize header files** that makes it easy to learn new Nuclei micro-controller products and improve software portability. This includes naming conventions for device-specific interrupts.
- **Methods for system initialization** to be used by each Device vendor. For example, the standardized *SystemInit()* (page 326) function is essential for configuring the clock system of the device.
- **Intrinsic functions** used to generate CPU instructions that are not supported by standard C functions.
- A variable *SystemCoreClock* (page 327) to determine the **system clock frequency** which simplifies the setup the timer.

The following sections provide details about the **NMSIS-Core**:

- *Using NMSIS in Embedded Applications* (page 6) describes the project setup and shows a simple program example
- *NMSIS-Core Device Templates* (page 12) describes the files of the *NMSIS Core* (page 5) in detail and explains how to adapt template files provided by Nuclei to silicon vendor devices.
- *NMSIS Core API* (page 57) describe the features and functions of the *Device Header File <device.h>* (page 47) in detail.
- *Register Define and Type Definitions* (page 77) describe the data structures of the *Device Header File <device.h>* (page 47) in detail.

2.1.2 Processor Support

NMSIS have provided support for all the Nuclei N/NX Class Processors.

Nuclei ISA Spec:

- Nuclei Process Core Instruction Set Architecture Spec⁴

Nuclei N Class Processor Reference Manuals:

- N200 series⁵
- N300 series⁶
- N600 series⁷

Nuclei NX Class Processor Reference Manuals:

- NX600 series⁸

2.1.3 Toolchain Support

The *NMSIS-Core Device Templates* (page 12) provided by Nuclei have been tested and verified using these toolchains:

- GNU Toolchain for RISC-V modified by Nuclei

2.2 Using NMSIS in Embedded Applications

2.2.1 Introduction

To use the **NMSIS-Core**, the following files are added to the embedded application:

- *Startup File* `startup_<device>.S` (page 14), which provided asm startup code and vector table.
- *Interrupt and Exception Handling File*: `intexc_<device>.S` (page 21), which provided general exception handling code for non-vector interrupts and exceptions.
- *Device Linker Script*: `gcc_<device>.ld` (page 31), which provided linker script for the device.
- *System Configuration Files* `system_<device>.c` and `system_<device>.h` (page 36), which provided general device configuration (i.e. for clock and BUS setup).
- *Device Header File* `<device.h>` (page 47) gives access to processor core and all peripherals.

Note: The files *Startup File* `startup_<device>.S` (page 14), *Interrupt and Exception Handling File*: `intexc_<device>.S` (page 21), *Device Linker Script*: `gcc_<device>.ld` (page 31) and *System Configuration Files* `system_<device>.c` and `system_<device>.h` (page 36) may require application specific adaptations and therefore should be copied into the application project folder prior configuration.

The *Device Header File* `<device.h>` (page 47) is included in all source files that need device access and can be stored on a central include folder that is generic for all projects.

The *Startup File* `startup_<device>.S` (page 14) is executed right after device reset, it will do necessary stack pointer initialization, exception and interrupt entry configuration, then call `SystemInit()` (page 326), after system initialization, will return to assemble startup code and do c/c++ runtime initialization which includes data, bss section initialization, c++ runtime initialization, then it will call `main()` function in the application code.

⁴ https://doc.nucleisys.com/nuclei_spec

⁵ <https://www.nucleisys.com/product.php?site=n200>

⁶ <https://www.nucleisys.com/product.php?site=n300>

⁷ <https://www.nucleisys.com/product.php?site=n600>

⁸ <https://www.nucleisys.com/product.php?site=nx600>

In the *Interrupt and Exception Handling File: `intexc_<device>.S`* (page 21), it will contain all exception and interrupt vectors and implements a default function for every interrupt. It may also contain stack and heap configurations for the user application.

The *System Configuration Files `system_<device>.c` and `system_<device>.h`* (page 36) performs the setup for the processor clock. The variable `SystemCoreClock` (page 327) indicates the CPU clock speed. *Systick Timer(`SysTimer`)* (page 278) describes the minimum feature set. In addition the file may contain functions for the memory BUS setup and clock re-configuration.

The *Device Header File `<device.h>`* (page 47) is the central include file that the application programmer is using in the C source code. It provides the following features:

- *Peripheral Access* (page 277) provides a standardized register layout for all peripherals. Optionally functions for device-specific peripherals may be available.
- *Interrupts and Exceptions* (page 284) can be accessed with standardized symbols and functions for the **ECLIC** are provided.
- *CPU Intrinsic Functions* (page 86) allow to access special instructions, for example for activating sleep mode or the NOP instruction.
- *Intrinsic Functions for SIMD Instructions* (page 93) provide access to the DSP-oriented instructions.
- *Systick Timer(`SysTimer`)* (page 278) function to configure and start a periodic timer interrupt.
- *Core CSR Register Access* (page 60) function to access the core csr registers.
- *Cache Functions* (page 308) to access the I-CACHE and D-CACHE unit
- *FPU Functions* (page 303) to access the Floating point unit.
- *PMP Functions* (page 306) to access the Physical Memory Protection unit
- *Version Control* (page 57) which defines NMSIS release specific macros.
- *Compiler Control* (page 59) is compiler agnostic `#define` symbols for generic C/C++ source code

The NMSIS-Core system files are device specific.

In addition, the *Startup File `startup_<device>.S`* (page 14) is also compiler vendor specific, currently only GCC version is provided. The versions provided by NMSIS are only generic templates. The adopted versions for a concrete device are typically provided by the device vendor through the according device family package.

For example, the following files are provided by the **GD32VF103** device family pack:

Fig. 1: NMSIS-Core User Files

Table 1: Files provided by GD32VF103 device family pack

File	Description
./Device/Source/GCC/startup_gd32vf103.S	Startup File startup_<device>.S for the GD32VF103 device variants.
./Device/Source/GCC/intexc_gd32vf103.S	Exception and Interrupt Handling File intexc_<device>.S for the GD32VF103 device variants.
./Device/Source/GCC/gcc_gd32vf103.ld	Linker script File gcc_<device>.ld for the GD32VF103 device variants.
./Device/Source/system_gd32vf103.c	System Configuration File system_<device>.c for the GD32VF103 device families
./Device/Include/system_gd32vf103.h	System Configuration File system_<device>.h for the GD32VF103 device families
./Device/Include/gd32vf103.h	Device Header File <device.h> for the GD32VF103 device families.

Note: The silicon vendors create these device-specific NMSIS-Core files based on *NMSIS-Core Device Templates* (page 12) provided by Nuclei.

Thereafter, the functions described under *NMSIS Core API* (page 57) can be used in the application.

2.2.2 Basic NMSIS Example

A typical example for using the NMSIS layer is provided below. The example is based on a GD32VF103 Device.

Listing 1: gd32vf103_example.c

```

1  #include <gd32vf103.h>                                // File name depends on device used
2
3  uint32_t volatile msTicks;                             // Counter for millisecond Interval
4  #define SysTick_Handler    eclic_mtip_handler
5  #define CONFIG_TICKS       (SOC_TIMER_FREQ / 1000)
6
7  void SysTick_Handler (void) {                          // SysTick Interrupt Handler
8      SysTick_Reload(CONFIG_TICKS);

```

(continues on next page)

(continued from previous page)

```

9      msTicks++;                                // Increment Counter
10 }
11
12 void WaitForTick (void) {
13     uint32_t curTicks;
14
15     curTicks = msTicks;                        // Save Current SysTick Value
16     while (msTicks == curTicks) {              // Wait for next SysTick Interrupt
17         __WFI ();                             // Power-Down until next Event/
18         ↪Interrupt
19     }
20 }
21
22 void TIMER0_UP_IRQHandler (void) {             // Timer Interrupt Handler
23     ;                                          // Add user code here
24 }
25
26 void timer0_init(int frequency) {              // Set up Timer (device specific)
27     ECLIC_SetPriorityIRQ (TIMER0_UP_IRQn, 1);  // Set Timer priority
28     ECLIC_EnableIRQ (TIMER0_UP_IRQn);         // Enable Timer Interrupt
29 }
30
31 void Device_Initialization (void) {            // Configure & Initialize MCU
32     if (SysTick_Config (CONFIG_TICKS)) {
33         ; // Handle Error
34     }
35     timer0_init ();                          // setup device-specific timer
36 }
37
38 // The processor clock is initialized by NMSIS startup + system file
39 void main (void) {                            // user application starts here
40     Device_Initialization ();                 // Configure & Initialize MCU
41     while (1) {                               // Endless Loop (the Super-Loop)
42         __disable_irq ();                     // Disable all interrupts
43         Get_InputValues ();                   // Read Values
44         __enable_irq ();                     // Enable all interrupts
45         Calculation_Response ();               // Calculate Results
46         Output_Response ();                   // Output Results
47         WaitForTick ();                       // Synchronize to SysTick Timer
48     }
49 }

```

2.2.3 Using Interrupt and Exception/NMI

Nuclei processors provide **NMI(Non-Maskable Interrupt)**, **Exception**, **Vector Interrupt** and **Non-Vector Interrupt** features.

2.2.4 Using NMSIS with generic Nuclei Processors

Nuclei provides NMSIS-Core files for the supported Nuclei Processors and for various compiler vendors. These files can be used when standard Nuclei processors should be used in a project. The table below lists the folder and device names of the Nuclei processors.

Table 2: Folder and device names of the Nuclei processors

Folder	Processor	RISC-V	Description
./Device/Nuclei/NUCLEI_N	<ul style="list-style-type: none"> • N200 • N300 • N600 	RV32	Contains Include and Source template files configured for the Nuclei N200/N300/N600 processor. The device name is NUCLEI_N and the name of the Device Header File <device.h> is <NUCLEI_N.h>.
./Device/Nuclei/NUCLEI_NX	NX600	RV64	Contains Include and Source template files configured for the Nuclei NX600 processor. The device name is NUCLEI_NX and the name of the Device Header File <device.h> is <NUCLEI_NX.h>.

2.2.5 Create generic Libraries with NMSIS

The NMSIS Processor and Core Peripheral files allow also to create generic libraries. The **NMSIS-DSP** Libraries are an example for such a generic library.

To build a generic library set the define `__NMSIS_GENERIC` and include the *nmsis_core.h* NMSIS CPU & Core Access header file for the processor.

The define `__NMSIS_GENERIC` disables device-dependent features such as the **SysTick timer** and the **Interrupt System**.

Example

The following code section shows the usage of the *nmsis_core.h* header files to build a generic library for N200, N300, N600, NX600.

One of these defines needs to be provided on the compiler command line.

By using this header file, the source code can access the functions for *Core CSR Register Access* (page 60), *CPU Intrinsic Functions* (page 86) and *Intrinsic Functions for SIMD Instructions* (page 93).

Listing 2: core_generic.h

```

1 #define __NMSIS_GENERIC    // Disable Eclic and SysTick functions
2 #include <nmsis_core.h>

```

2.3 NMSIS-Core Device Templates

2.3.1 Introduction

Nuclei supplies NMSIS-Core device template files for the all supported Nuclei N/NX Class Processors and various compiler vendors. Refer to the list of *supported toolchain* (page 6) for compliance.

These NMSIS-Core device template files include the following:

- Register names of the Core Peripherals and names of the Core Exception/Interrupt Vectors.
- Functions to access core peripherals, special CPU instructions and SIMD instructions
- Generic startup code and system configuration code.

The detailed file structure of the NMSIS-Core device templates is shown in the following picture.

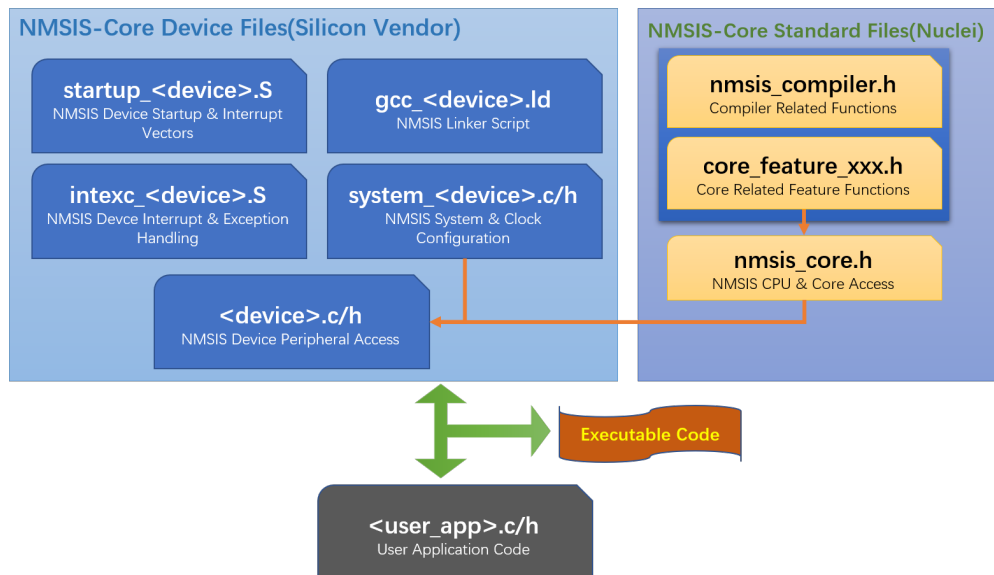

Fig. 2: NMSIS-Core Device Templates

2.3.2 NMSIS-Core Processor Files

The NMSIS-Core processor files provided by Nuclei are in the directory *NMSIS/Core/Include*.

These header files define all processor specific attributes do not need any modifications.

The *nmsis_core.h* defines the core peripherals and provides helper functions that access the core registers.

2.3.3 Device Examples

The NMSIS Software Pack defines several devices that are based on the Nuclei N/NX processors.

The device related NMSIS-Core files are in the directory *Device/Nuclei* and include NMSIS-Core processor file explained before.

The following sample devices are defined as below:

Table 3: Device Examples of Nuclei Processor

Family	Device	Description
Nuclei N	NUCLEI N Class	Nuclei N Class based device
Nuclei NX	NUCLEI NX Class	Nuclei NX Class based device

2.3.4 Template Files

To simplify the creation of NMSIS-Core device files, the following template files are provided that should be extended by the silicon vendor to reflect the actual device and device peripherals.

Silicon vendors add to these template files the following information:

- **Device Peripheral Access Layer** that provides definitions for device-specific peripherals.
- **Access Functions for Peripherals** (optional) that provides additional helper functions to access device-specific peripherals.
- **Interrupt vectors** in the startup file that are device specific.

Table 4: NMSIS-Core Device Template Files

Template File (Under <i>./Device/_Template_Vendor/Vendor/</i>)	Description
<i>Device/Source/GCC/startup_Device.S</i>	Startup file template for GNU GCC RISC-V Embedded Compiler.
<i>Device/Source/GCC/gcc_Device.ld</i>	Link Script file template for GNU GCC RISC-V Embedded Compiler.
<i>Device/Source/GCC/intexc_Device.S</i>	Exception and Interrupt handling file template for GNU GCC RISC-V Embedded Compiler.
<i>Device/Source/system_Device.c</i>	Generic <i>system_Device.c</i> file for system configuration (i.e. processor clock and memory bus system).
<i>Device/Include/Device.h</i>	Generic device header file. Needs to be extended with the device-specific peripheral registers. Optionally functions that access the peripherals can be part of that file.
<i>Device/Include/system_Device.h</i>	Generic system device configuration include file.

Note: The template files for silicon vendors are placed under *./Device/_Template_Vendor/Vendor/*.

Please goto that folder to find the file list in the above table.

2.3.5 Adapt Template Files to a Device

The following steps describe how to adopt the template files to a specific device or device family.

Copy the complete all files in the template directory and replace:

- directory name `Vendor` with the abbreviation for the device vendor e.g.: **GD**.
- directory name `Device` with the specific device name e.g.: **GD32VF103**.
- in the file names `Device` with the specific device name e.g.: **GD32VF103**.

Each template file contains comments that start with **TODO**: that describe a required modification.

The template files contain place holders:

Table 5: Placeholders of Template files

Placeholder	Replaced with
<Device>	the specific device name or device family name; i.e. GD32VF103.
<DeviceInterrupt>	a specific interrupt name of the device; i.e. TIM1 for Timer 1.
<DeviceAbbreviation>	short name or abbreviation of the device family; i.e. GD32VF.
Nuclei-N#	the specific Nuclei Class name; i.e. Nuclei N or Nuclei NX.

2.3.6 Device Templates Explanation

The device configuration of the template files is described in detail on the following pages:

Startup File `startup_<device>.S`

The Startup File `startup_<device>.S` contains:

- The reset handler which is executed after CPU reset and typically calls the `SystemInit()` (page 326) function.
- The setup values for the stack pointer SP.
- Exception vectors of the Nuclei Processor with weak functions that implement default routines.
- Interrupt vectors that are device specific with weak functions that implement default routines.

The processor level start flow is implemented in the `startup_<device>.S`. Detail description as below picture:

Stage1: Interrupt and Exception initialization

- Disable Interrupt
- Initialize GP, stack
- Initialize NMI entry and set default NMI handler
- Initialize Exception entry and set default exception handler
- Initialize vector table entry and set default interrupt handler
- Initialize Interrupt mode as ECLIC mode. (ECLIC mode is proposed. Default mode is CLINT mode)

Stage2: Hardware initialization

- Enable FPU if necessary
- Call user defined `SystemInit()` (page 326) for system clock initialization.

Stage3: Section initialization

- Copy section, e.g. data section, text section if necessary.
- Clear Block Started by Symbol (BSS) section
- Call `__libc_fini_array` and `__libc_init_array` functions to do C library initialization

- Call `_premain_init` function to do initialization steps before main function
- Jump Main

The file exists for each supported toolchain and is the only toolchain specific NMSIS file.

To adapt the file to a new device only the interrupt vector table needs to be extended with the device-specific interrupt handlers.

The naming convention for the interrupt handler names are `eclic_<interrupt_name>_handler`.

This table needs to be consistent with `IRQn_Type` that defines all the IRQ numbers for each interrupt.

The following example shows the extension of the interrupt vector table for the GD32VF103 device family.

```

1      .section .vtable
2
3      .weak  eclic_msip_handler
4      .weak  eclic_mtip_handler
5      .weak  eclic_pmaf_handler
6      /* Adjusted for GD32VF103 interrupt handlers */
7      .weak  eclic_wwdgt_handler
8      .weak  eclic_lvd_handler
9      .weak  eclic_tamper_handler
10     :      :
11     :      :
12     .weak  eclic_can1_ewmc_handler
13     .weak  eclic_usbfs_handler
14
15     .globl vector_base
16     .type vector_base, @object
17 vector_base:
18     /* Run in FlashXIP download mode */
19     j _start                                     /* 0: Reserved, Jump to _
20     ↳start when reset for vector table not remapped cases.*/
21     .align LOG_REGBYTES                         /*    Need to align 4_
22     ↳byte for RV32, 8 Byte for RV64 */
23     DECLARE_INT_HANDLER    default_intexc_handler    /* 1: Reserved */
24     DECLARE_INT_HANDLER    default_intexc_handler    /* 2: Reserved */
25     DECLARE_INT_HANDLER    eclic_msip_handler        /* 3: Machine software_
26     ↳interrupt */
27     :          :

Interrupt and Exception Handling File: intexc_<device>.S

The intexc File intexc_<device>.S contains:

- Macro to save caller register.
- Macro to restore caller register.
- Default Exception/NMI routine implementation.
- Default Non-Vector Interrupt routine implementation.

Nuclei processors provide **NMI(Non-Maskable Interrupt)**, **Exception**, **Vector Interrupt** and **Non-Vector Interrupt** features.

NMI(Non-Maskable Interrupt)

Click [NMI⁹](https://doc.nucleisys.com/nuclei_spec/isa/nmi.html) to learn about Nuclei Processor Core NMI in Nuclei ISA Spec.

NMI is used for urgent external HW error. It can't be masked and disabled.

When NMI happened, bit 9 of CSR MMSIC_CTL will be checked. If this bit value is 1, then NMI entry address will be the same as exception(CSR_MTVEC), and exception code for NMI will be 0xFFFF, otherwise NMI entry will be same as reset_vector.

In NMSIS-Core, the bit 9 of CSR MMISC_CTL is set to 1 during core startup, so NMI will be treated as Exception and handled.

⁹ https://doc.nucleisys.com/nuclei_spec/isa/nmi.html

Exception

Click [Exception¹⁰](#) to learn about Nuclei Processor Core Exception in Nuclei ISA Spec.

For CPU exception, the entry for exception will be `exc_entry`, in this entry code, it will call default exception handler `core_exception_handler()` (page 328).

In the common exception routine(`exc_entry`) to get more information like exception code. Exception handle flow show as below picture:

Fig. 3: Exception Handling Flow

NMI and exception could support nesting. Two levels of NMI/Exception state save stacks are supported.

We support three nesting mode as below:

- NMI nesting exception
- Exception nesting exception
- Exception nesting NMI

For software, we have provided the common entry for NMI and exception. Silicon vendor only need adapt the interface defined in *Interrupt Exception NMI Handling* (page 327).

Context save and restore have been handled by `exc_entry` interface.

When exception exception return it will run the intruction which trigger the exception again. It will cause software dead loop. So in the exception handler for each exception code, we propose to set CSR `MEPC` to be `MEPC+4`, then it will start from next instruction of `MEPC`.

¹⁰ https://doc.nucleisys.com/nuclei_spec/isa/exception.html

Interrupt

Click [Interrupt¹¹](#) to learn about Nuclei Processor Core Interrupt in Nuclei Spec.

Interrupt could be configured as **CLINT** mode or **ECILC** mode.

In NMSIS-Core, Interrupt has been configured as **ECLIC** mode during startup in *startup_<Devices>.S*, which is also recommended setting using Nuclei Processors.

ECLIC managed interrupt could be configured as **vector** and **non-vector** mode.

Detail interrupt handling process as below picture:

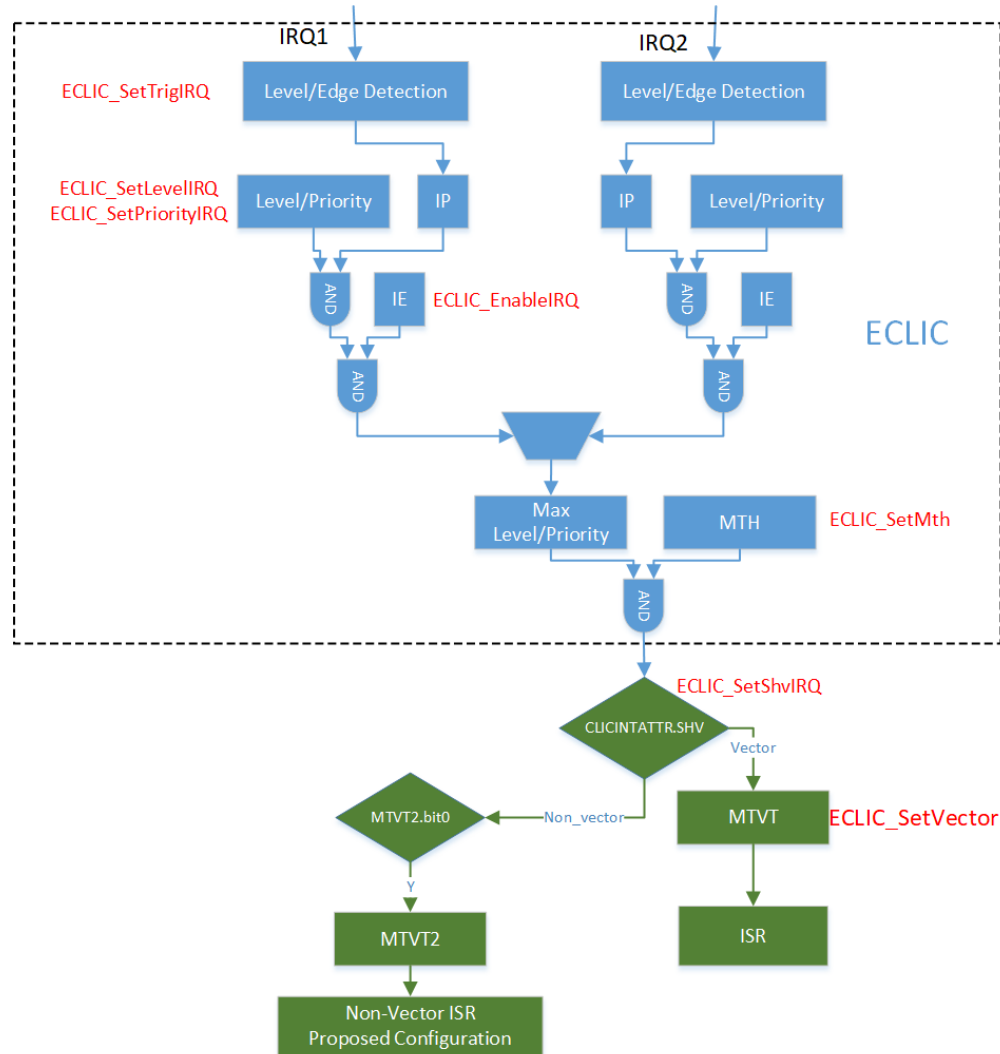

Fig. 4: Interrupt Handling Flow

To get highest priority interrupt we need compare the interrupt level first. If level is the same then compare the priority. High level interrupt could interrupt low level ISR and trigger interrupt nesting. If different priority with same level interrupt pending higher priority will be served first. Interrupt could be configured as vector mode and non-vector mode by vendor. For non-vector mode interrupt handler entry get from MTVT2 and exception/NMI handler entry get

¹¹ https://doc.nucleisys.com/nuclei_spec/isa/interrupt.html

from MTVEC. If Vendor need set non vector mode interrupt handler entry from MTVVEC you need set MTVT2.BIT0 as 0.

Non-Vector Interrupt SW handler

For **non-vector** mode interrupt it will make the necessary CSR registers and context save and restore. Non-vector mode software handle flow show as below picture:

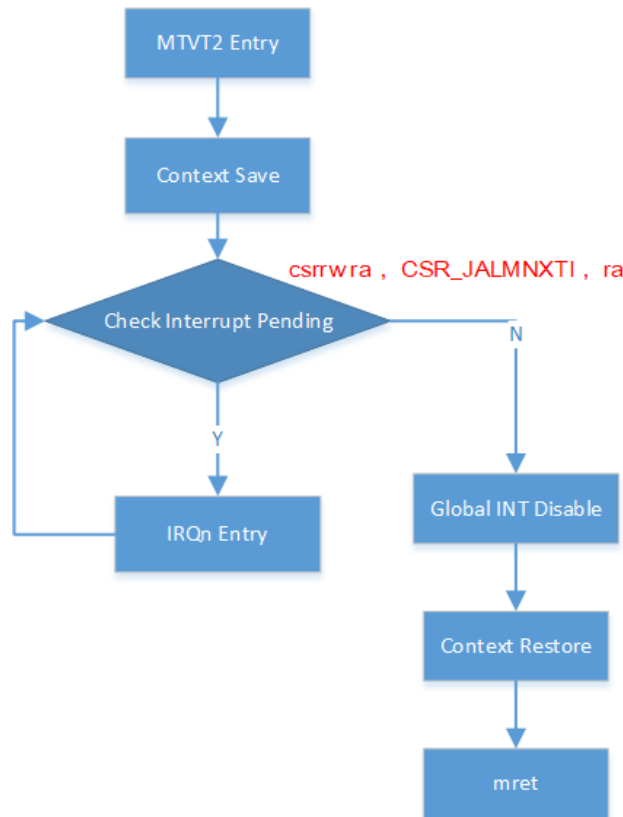

Fig. 5: Non-vector mode interrupt software handle flow

Detail description for non-vector mode interrupt handler as below steps:

1. Get non-vector mode handler entry from MTVT2 if MTVT2.BIT0 is 1(proposed configuration).
2. Context save to stack for cpu registers.
3. Save CSR registers MEPC/MCAUSE/MSUBM to stack.
4. Run instruction `csrrw ra, CSR_JALMNXTI, ra`. It will enable interrupt, check interrupt pending. If interrupt is pending then get highest priority interrupt and jump to interrupt handler entry in the vector table, otherwise it will go to step 6.
5. Execute the interrupt handler routine, when return from isr routine it will jump to step 4.
6. Global interrupt disable.
7. Restore CSR registers MEPC/MCAUSE/MSUBM.
8. Context restore from stack for cpu registers.
9. Execute `mret` to return from handler.

For **non-vector** mode interrupt it could support **interrupt nesting**.

Interrupt nesting handle flow show as below picture:

Fig. 6: Nesting interrupt handling flow

Vector Interrupt SW handler

If vector interrupt handler need support nesting or making function call Vector mode software handling flow show as below picture:

Fig. 7: Vector mode nesting interrupt handling flow

Detail description for nested vector mode interrupt handler as below steps:

1. Get vector mode handler from address of vector table entry MTVT added offset.
2. Context save to stack for cpu registers, done in each vector interrupt handler via `__INTERRUPT` (page 60)

3. Save CSR registers MEPC/MCAUSE/MSUBM to stack, done in each vector interrupt handler by read and save these CSRs into variables.
4. Execute the interrupt handling.
5. Restore CSR registers MEPC/MCAUSE/MSUBM from stack.
6. CSR registers restore from saved variables used in step 3.
7. Execute `mret` to return from handler

Here is sample code for above nested vector interrupt handling process:

```

1 // Vector interrupt handler for on-board button
2 __INTERRUPT void SOC_BUTTON_1_HANDLER(void)
3 {
4     // save mepc,mcause,msubm enable interrupts
5     SAVE_IRQ_CSR_CONTEXT();
6
7     printf("%s", "----Begin button1 handler----Vector mode\r\n");
8
9     // Green LED toggle
10    gpio_toggle(GPIO, SOC_LED_GREEN_GPIO_MASK);
11
12    // Clear the GPIO Pending interrupt by writing 1.
13    gpio_clear_interrupt(GPIO, SOC_BUTTON_1_GPIO_OFS, GPIO_INT_RISE);
14
15    wait_seconds(1); // Wait for a while
16
17    printf("%s", "----End button1 handler\r\n");
18
19    // disable interrupts, restore mepc,mcause,msubm
20    RESTORE_IRQ_CSR_CONTEXT();
21 }

```

Detail description for non-nested vector mode interrupt handler as below

To improve the software response latency for vector mode vendor could remove context save/restore and **MEPC/MCAUSE/MSUBM** save/restore.

If so vector mode interrupt will not support nesting and interrupt handler can only be a leaf function which doesn't make any function calls.

Then the vector mode interrupt software flow will be described as below:

1. Get vector mode handler from address of vector table entry MTVT added offset.
2. Execute the interrupt handler(leaf function).
3. Execute `mret` to return from handler

Here is sample code for above non-nested vector interrupt handler which is a leaf function handling process:

```

1 static uint32_t btn_pressed = 0;
2 // Vector interrupt handler for on-board button
3 // This function is an leaf function, no function call is allowed
4 __INTERRUPT void SOC_BUTTON_1_HANDLER(void)
5 {
6     btn_pressed++;
7 }

```

intexc_Device.S Template File

The file exists for each supported toolchain and is the only toolchain specific NMSIS file.

Normally this file needn't adapt for different device. If CPU CSR registers have done some changes you may need some adaption.

Here we provided `intexc_Device.S` template file as below:

```

Device Linker Script: gcc_<device>.ld

The Linker Script File gcc_<device>.ld contains:

- Memory base address and size.
- Code, data section, vector table etc. location.
- Stack & heap location and size.

The file exists for each supported toolchain and is the only toolchain specific NMSIS file.

To adapt the file to a new device only when you need change the memory base address, size, data and code location etc.

gcc_Device.ld Template File

Here we provided gcc_Device.ld template file as below:

System Configuration Files `system_<device>.c` and `system_<device>.h`

The **System Configuration Files** `system_<device>.c` and `system_<device>.h` provides as a minimum the functions described under *System Device Configuration* (page 325).

These functions are device specific and need adaptations. In addition, the file might have configuration settings for the device such as XTAL frequency or PLL prescaler settings, necessary system initialization, vendor customized interrupt, exception and nmi handling code, refer to *System Device Configuration* (page 325) for more details.

For devices with external memory BUS the `system_<device>.c` also configures the BUS system.

The silicon vendor might expose other functions (i.e. for power configuration) in the `system_<device>.c` file. In case of additional features the function prototypes need to be added to the `system_<device>.h` header file.

system_Device.c Template File

Here we provided `system_Device.c` template file as below:

```

39  /**
40   * \defgroup NMSIS_Core_SystemConfig      System Device Configuration
41   * \brief Functions for system init, clock setup and interrupt/exception/nmi_
42   *        functions available in system_<device>.c.
43   * \details
44   * Nuclei provides a template file **system_Device.c** that must be adapted by
45   * the silicon vendor to match their actual device. As a <b>minimum requirement</b>,
46   * this file must provide:
47   * - A device-specific system configuration function, \ref SystemInit.
48   * - A global variable that contains the system frequency, \ref SystemCoreClock.
49   * - A global eclic configuration initialization, \ref ECLIC_Init.
50   * - Global c library \ref _init and \ref _fini functions called right before_
51   *   calling main function.
52   * - Vendor customized interrupt, exception and nmi handling code, see \ref NMSIS_
53   *   Core_IntExcNMI_Handling
54   *
55   * The file configures the device and, typically, initializes the oscillator (PLL)_
56   * that is part
57   * of the microcontroller device. This file might export other functions or variables_
58   * that provide
59   * a more flexible configuration of the microcontroller system.
60   *
61   * And this file also provided common interrupt, exception and NMI exception handling_
62   * framework template,
63   * Silicon vendor can customize these template code as they want.
64   *
65   * \note Please pay special attention to the static variable \c SystemCoreClock. This_
66   *   variable might be
67   *   used throughout the whole system initialization and runtime to calculate frequency/_
68   *   time related values.
69   *   Thus one must assure that the variable always reflects the actual system clock_
70   *   speed.

```

(continues on next page)

(continued from previous page)

```

62  *
63  * \attention
64  * Be aware that a value stored to \c SystemCoreClock during low level initialization,
65  * (i.e. \c SystemInit()) might get
66  * overwritten by C library startup code and/or .bss section initialization.
67  * Thus its highly recommended to call \ref SystemCoreClockUpdate at the beginning of,
68  * the user \c main() routine.
69  *
70  * @{
71  */
72  /*-----
73  System Core Clock Variable
74  *-----*/

Device Header File <device.h>

The *Device Header File <device.h>* (page 47) contains the following sections that are device specific:

- *Interrupt Number Definition* (page 47) provides interrupt numbers (IRQn) for all exceptions and interrupts of the device.
- *Configuration of the Processor and Core Peripherals* (page 48) reflect the features of the device.
- *Device Peripheral Access Layer* (page 50) provides definitions for the *Peripheral Access* (page 277) to all device peripherals. It contains all data structures and the address mapping for device-specific peripherals.
- **Access Functions for Peripherals (optional)** provide additional helper functions for peripherals that are useful for programming of these peripherals. Access Functions may be provided as inline functions or can be extern references to a device-specific library provided by the silicon vendor.

NMSIS Core API (page 57) describes the standard features and functions of the *Device Header File <device.h>* (page 47) in detail.

Interrupt Number Definition

Device Header File <device.h> (page 47) contains the enumeration **IRQn_Type** that defines all exceptions and interrupts of the

- Negative IRQn values represent processor core exceptions (internal interrupts).
- Positive IRQn values represent device-specific exceptions (external interrupts). The first device-specific interrupt has the IRQn value 0. The IRQn values needs extension to reflect the device-specific interrupt vector table in the *Startup File startup_<device>.S* (page 14).

The following example shows the extension of the interrupt vector table for the GD32VF103 device family.

```

1  typedef enum IRQn {
2      /***** N200 Processor Exceptions Numbers_
    ↪ *****/
3      Reserved0_IRQn      = 0,      /*!< Internal reserved_
    ↪ */
4      Reserved1_IRQn      = 1,      /*!< Internal reserved_
    ↪ */
5      Reserved2_IRQn      = 2,      /*!< Internal reserved_
    ↪ */
6      SysTimerSW_IRQn     = 3,      /*!< System Timer SW interrupt_
    ↪ */
7      Reserved3_IRQn      = 4,      /*!< Internal reserved_
    ↪ */

```

(continues on next page)

(continued from previous page)

```

8   Reserved4_IRQn      = 5,      /*!< Internal reserved
↳   */
9   Reserved5_IRQn      = 6,      /*!< Internal reserved
↳   */
10  SysTimer_IRQn       = 7,      /*!< System Timer Interrupt
↳   */
11  Reserved6_IRQn      = 8,      /*!< Internal reserved
↳   */
12  Reserved7_IRQn      = 9,      /*!< Internal reserved

25  LVD_IRQn            = 20,     /*!< LVD through EXTI line detect
↳  interrupt */
26  TAMPER_IRQn         = 21,     /*!< tamper through EXTI line detect
↳   */
27      :                :
28      :                :
29  CAN1_EWMC_IRQn      = 85,     /*!< CAN1 EWMC interrupt
↳   */
30  USBFS_IRQn          = 86,     /*!< USBFS global interrupt
↳   */
31  SOC_INT_MAX,        /*!< Number of total Interrupts
↳   */
32 } IRQn_Type;

```

Configuration of the Processor and Core Peripherals

The *Device Header File* <device.h> (page 47) configures the Nuclei N/NX Class Processors and the core peripherals with #define that are set prior to including the file *nmsis_core.h*.

The following tables list the #define along with the possible values for N200, N300, N600, NX600. If these #define are missing default values are used.

nmsis_core.h

Table 6: Macros used in nmsis_core.h

#define	Value Range	Default	Description
__NUCLEI_N_REV OR __NUCLEI_NX_REV	0x0100 0x0104	0x0100	<ul style="list-style-type: none"> For Nuclei N class device, define __NUCLEI_N_REV, for NX class device, define __NUCLEI_NX_REV. Core revision number ([15:8] revision number, [7:0] patch number), 0x0100 -> 1.0, 0x0104 -> 1.4
__SYSTIMER_PRESENT	0 .. 1	1	Define whether Private System Timer is present or not. This SysTimer is a Memory Mapped Unit.
__SYSTIMER_BASEADDR	.	0x02000000	Base address of the System Timer Unit.
__ECLIC_PRESENT	0 .. 1	1	Define whether Enhanced Core Local Interrupt Controller (ECLIC) Unit is present or not
__ECLIC_BASEADDR	.	0x0C000000	Base address of the ECLIC unit.
__ECLIC_INTCTLBITS	1 .. 8	1	Define the number of hardware bits are actually implemented in the clicintctl registers.
__ECLIC_INTNUM	1 .. 1024	1	Define the total interrupt number(including the internal core interrupts) of ECLIC Unit
__PMP_PRESENT	0 .. 1	0	Define whether Physical Memory Protection (PMP) Unit is present or not.
__PMP_ENTRY_NUM	8 or 16	8	Define the numbers of PMP entries.
__FPU_PRESENT	0 .. 2	0	Define whether Floating Point Unit (FPU) is present or not. <ul style="list-style-type: none"> 0: Not present 1: Single precision FPU present 2: Double precision FPU present
__DSP_PRESENT	0 .. 1	0	Define whether Digital Signal Processing Unit (DSP) is present or not.
__ICACHE_PRESENT	0 .. 1	0	Define whether I-Cache Unit is present or not.
__DCACHE_PRESENT	0 .. 1	0	Define whether D-Cache Unit is present or not.
__Vendor_SysTickConfig	0 .. 1	0	If __SYSTIMER_PRESENT is 1, then the __Vendor_SysTickConfig can be set to 0, otherwise it can only set to 1. If this define is set to 1, then the default SysTick_Config and SysTick_Reload function is excluded. In this case, the file Device.h must contain a vendor specific implementation of this function.

NMSIS Version and Processor Information

The following shows the defines in the *nmsis_core.h* file that may be used in the *NMSIS-Core Device Templates* (page 12) to verify a minimum version or ensure that the right Nuclei N/NX class is used.

Device Peripheral Access Layer

The *Device Header File* `<device.h>` (page 47) contains for each peripheral:

- Register Layout Typedef
- Base Address
- Access Definitions

The section *Peripheral Access* (page 277) shows examples for peripheral definitions.

Device.h Template File

Here we provided `Device.h` template file as below:

2.4 Register Mapping

The table below associates some common register names used in NMSIS to the register names used in [Nuclei ISA Spec](#)¹².

Table 7: Register names used in NMSIS related with the register names in ISA

NMSIS Register Name	N200, N300, N600, NX600	Register Description
Enhanced Core Local Interrupt Controller(ECLIC)		
ECLIC->CFG	cliccfg	ECLIC Global Configuration Register
ECLIC->INFO	clicinfo	ECLIC Global Information Register
ECLIC->MTH	mtm	ECLIC Global Machine Mode Threshold Register
ECLIC->CTRL[i].INTIP	clicintip[i]	ECLIC Interrupt Pending Register
ECLIC->CTRL[i].INTIE	clicintie[i]	ECLIC Interrupt Enable Register
ECLIC->CTRL[i].INTATTR	clicintattr[i]	ECLIC Interrupt Attribute Register
ECLIC->CTRL[i].INTCTRL	clicintctl[i]	ECLIC Interrupt Input Control Register
System Timer Unit(SysTimer)		
SysTimer->MTIMER	mtime_hi<<32 + mtime_lo	System Timer current value 64bits Register
SysTimer->MTIMERCMP	mtimecmp_hi<<32 + mtimecmp_lo	System Timer compare value 64bits Register
SysTimer->MSTOP	mstop	System Timer Stop Register
SysTimer->MSIP	msip	System Timer SW interrupt Register

2.5 NMSIS Core API

If you want to access doxygen generated NMSIS Core API, please click [NMSIS Core Doxygen API Documentation](#).

2.5.1 Version Control

group NMSIS_Core_VersionControl

Version #define symbols for NMSIS release specific C/C++ source code.

We followed the [semantic versioning 2.0.0](#)¹³ to control NMSIS version. The version format is **MAJOR.MINOR.PATCH**, increment the:

1. MAJOR version when you make incompatible API changes,
2. MINOR version when you add functionality in a backwards compatible manner, and
3. PATCH version when you make backwards compatible bug fixes.

¹² https://doc.nucleisys.com/nuclei_spec/

¹³ <https://semver.org/>

The header file `nmsis_version.h` is included by each core header so that these definitions are available.

Example Usage for NMSIS Version Check:

```
#if defined(__NMSIS_VERSION) && (__NMSIS_VERSION >= 0x00010105)
    #warning "Yes, we have NMSIS 1.1.5 or later"
#else
    #error "We need NMSIS 1.1.5 or later!"
#endif
```

Unnamed Group**__NUCLEI_N_REV (0x0104)**

Nuclei N class core revision number.

Reversion number format: [15:8] revision number, [7:0] patch number

Attention This define is exclusive with [__NUCLEI_NX_REV](#) (page 58)

__NUCLEI_NX_REV (0x0100)

Nuclei NX class core revision number.

Reversion number format: [15:8] revision number, [7:0] patch number

Attention This define is exclusive with [__NUCLEI_N_REV](#) (page 58)

Defines**__NMSIS_VERSION_MAJOR (1U)**

Represent the NMSIS major version.

The NMSIS major version can be used to differentiate between NMSIS major releases.

__NMSIS_VERSION_MINOR (0U)

Represent the NMSIS minor version.

The NMSIS minor version can be used to query a NMSIS release update including new features.

__NMSIS_VERSION_PATCH (1U)

Represent the NMSIS patch version.

The NMSIS patch version can be used to show bug fixes in this package.

__NMSIS_VERSION (([__NMSIS_VERSION_MAJOR](#) (page 58) << 16U) | ([__NMSIS_VERSION_MINOR](#) << 8) | [__NMSIS_VERSION_PATCH](#))

Represent the NMSIS Version.

NMSIS Version format: **MAJOR.MINOR.PATCH**

- MAJOR: [__NMSIS_VERSION_MAJOR](#) (page 58), stored in bits [31:16] of [__NMSIS_VERSION](#) (page 58)
- MINOR: [__NMSIS_VERSION_MINOR](#) (page 58), stored in bits [15:8] of [__NMSIS_VERSION](#) (page 58)
- PATCH: [__NMSIS_VERSION_PATCH](#) (page 58), stored in bits [7:0] of [__NMSIS_VERSION](#) (page 58)

2.5.2 Compiler Control

group **NMSIS_Core_CompilerControl**

Compiler agnostic #define symbols for generic c/c++ source code.

The NMSIS-Core provides the header file **nmsis_compiler.h** with consistent #define symbols for generate C or C++ source files that should be compiler agnostic. Each NMSIS compliant compiler should support the functionality described in this section.

The header file **nmsis_compiler.h** is also included by each Device Header File <device.h> so that these definitions are available.

Defines

__has_builtin (x) (0)

__ASM __asm

Pass information from the compiler to the assembler.

__INLINE inline

Recommend that function should be inlined by the compiler.

__STATIC_INLINE static inline

Define a static function that may be inlined by the compiler.

__STATIC_FORCEINLINE __attribute__((always_inline)) static inline

Define a static function that should be always inlined by the compiler.

__NO_RETURN __attribute__((__noreturn__))

Inform the compiler that a function does not return.

__USED __attribute__((used))

Inform that a variable shall be retained in executable image.

__WEAK __attribute__((weak))

restrict pointer qualifier to enable additional optimizations.

__VECTOR_SIZE (x) __attribute__((vector_size(x)))

specified the vector size of the variable, measured in bytes

__PACKED __attribute__((packed, aligned(1)))

Request smallest possible alignment.

__PACKED_STRUCT struct __attribute__((packed, aligned(1)))

Request smallest possible alignment for a structure.

__PACKED_UNION union __attribute__((packed, aligned(1)))

Request smallest possible alignment for a union.

__UNALIGNED_UINT16_WRITE (addr, val) (void)((((struct *T_UINT16_WRITE* (page 60) *) (void *) (addr))->v) = (val))

Pointer for unaligned write of a uint16_t variable.

__UNALIGNED_UINT16_READ (addr) (((const struct *T_UINT16_READ* (page 60) *) (const void *) (addr))->v)

Pointer for unaligned read of a uint16_t variable.

__UNALIGNED_UINT32_WRITE (addr, val) (void)((((struct *T_UINT32_WRITE* (page 60) *) (void *) (addr))->v) = (val))

Pointer for unaligned write of a uint32_t variable.

__UNALIGNED_UINT32_READ (addr) (((const struct *T_UINT32_READ* (page 60) *) (const void *) (addr)) -> v)
Pointer for unaligned read of a uint32_t variable.

__ALIGNED (x) __attribute__((aligned(x)))
Minimum x bytes alignment for a variable.

__RESTRICT __restrict
restrict pointer qualifier to enable additional optimizations.

__COMPILER_BARRIER () __ASM (page 59) volatile(“”:”:”memory”)
Barrier to prevent compiler from reordering instructions.

__USUALLY (exp) __builtin_expect((exp), 1)
provide the compiler with branch prediction information, the branch is usually true

__RARELY (exp) __builtin_expect((exp), 0)
provide the compiler with branch prediction information, the branch is rarely true

__INTERRUPT __attribute__((interrupt))
Use this attribute to indicate that the specified function is an interrupt handler.

Variables

__PACKED_STRUCT T_UINT16_WRITE
Packed struct for unaligned uint16_t write access.

__PACKED_STRUCT T_UINT16_READ
Packed struct for unaligned uint16_t read access.

__PACKED_STRUCT T_UINT32_WRITE
Packed struct for unaligned uint32_t write access.

__PACKED_STRUCT T_UINT32_READ
Packed struct for unaligned uint32_t read access.

2.5.3 Core CSR Register Access

Click [Nuclei Core CSR](#)¹⁴ to learn about Core CSR in Nuclei ISA Spec.

group **NMSIS_Core_CSR_Register_Access**

Functions to access the Core CSR Registers.

The following functions or macros provide access to Core CSR registers.

- *Core CSR Encodings* (page 70)
- *Core CSR Registers* (page 63)

Defines

__RV_CSR_SWAP (csr, val)
CSR operation Macro for csrrw instruction.
Read the content of csr register to __v, then write content of val into csr register, then return __v
Return the CSR register value before written

¹⁴ https://doc.nucleisys.com/nuclei_spec/isa/core_csr.html

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)
- `val`: value to store into the CSR register

__RV_CSR_READ (`csr`)

CSR operation Macro for csrr instruction.

Read the content of csr register to `__v` and return it

Return the CSR register value

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)

__RV_CSR_WRITE (`csr`, `val`)

CSR operation Macro for csrw instruction.

Write the content of `val` to csr register

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)
- `val`: value to store into the CSR register

__RV_CSR_READ_SET (`csr`, `val`)

CSR operation Macro for csrrs instruction.

Read the content of csr register to `__v`, then set csr register to be `__v | val`, then return `__v`

Return the CSR register value before written

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)
- `val`: Mask value to be used with csrrs instruction

__RV_CSR_SET (`csr`, `val`)

CSR operation Macro for csrs instruction.

Set csr register to be `csr_content | val`

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)
- `val`: Mask value to be used with csrs instruction

__RV_CSR_READ_CLEAR (`csr`, `val`)

CSR operation Macro for csrrc instruction.

Read the content of csr register to `__v`, then set csr register to be `__v & ~val`, then return `__v`

Return the CSR register value before written

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)

- `val`: Mask value to be used with `csrrc` instruction

__RV_CSR_CLEAR (`csr`, `val`)

CSR operation Macro for `csrrc` instruction.

Set `csr` register to be `csr_content` & `~val`

Parameters

- `csr`: CSR macro definition defined in *Core CSR Registers* (page 63), eg. `CSR_MSTATUS` (page 64)
- `val`: Mask value to be used with `csrrc` instruction

Functions

__STATIC_FORCEINLINE void __enable_irq(void)

Enable IRQ Interrupts.

Enables IRQ interrupts by setting the MIE-bit in the MSTATUS Register.

Remark Can only be executed in Privileged modes.

__STATIC_FORCEINLINE void __disable_irq(void)

Disable IRQ Interrupts.

Disables IRQ interrupts by clearing the MIE-bit in the MSTATUS Register.

Remark Can only be executed in Privileged modes.

__STATIC_FORCEINLINE uint64_t __get_rv_cycle(void)

Read whole 64 bits value of `mcycle` counter.

This function will read the whole 64 bits of `MCYCLE` register

Return The whole 64 bits value of `MCYCLE`

Remark It will work for both RV32 and RV64 to get full 64bits value of `MCYCLE`

__STATIC_FORCEINLINE uint64_t __get_rv_instret(void)

Read whole 64 bits value of machine instruction-retired counter.

This function will read the whole 64 bits of `MINSTRET` register

Return The whole 64 bits value of `MINSTRET`

Remark It will work for both RV32 and RV64 to get full 64bits value of `MINSTRET`

__STATIC_FORCEINLINE uint64_t __get_rv_time(void)

Read whole 64 bits value of real-time clock.

This function will read the whole 64 bits of `TIME` register

Return The whole 64 bits value of `TIME` CSR

Remark It will work for both RV32 and RV64 to get full 64bits value of `TIME`

Attention only available when user mode available

2.5.4 Core CSR Encoding

Click [Nuclei Core CSR¹⁵](https://doc.nucleisys.com/nuclei_spec/isa/core_csr.html) to learn about Core CSR in Nuclei ISA Spec.

2.5.5 Register Define and Type Definitions

group **NMSIS_Core_Registers**

Type definitions and defines for core registers.

Defines

__RISCV_XLEN 32

Refer to the width of an integer register in bits(either 32 or 64)

Typedefs

typedef uint32_t **rv_csr_t**

Type of Control and Status Register(CSR), depends on the XLEN defined in RISC-V.

Core

group **NMSIS_Core_Base_Registers**

Type definitions and defines for base core registers.

union CSR_MISA_Type

#include <core_feature_base.h> Union type to access MISA register.

Public Members

rv_csr_t (page 78) **a**

bit: 0 Atomic extension

rv_csr_t (page 78) **b**

bit: 1 Tentatively reserved for Bit-Manipulation extension

rv_csr_t (page 78) **c**

bit: 2 Compressed extension

rv_csr_t (page 78) **d**

bit: 3 Double-precision floating-point extension

Type used for csr data access.

rv_csr_t (page 78) **e**

bit: 4 RV32E base ISA

rv_csr_t (page 78) **f**

bit: 5 Single-precision floating-point extension

rv_csr_t (page 78) **g**

bit: 6 Additional standard extensions present

rv_csr_t (page 78) **h**

bit: 7 Hypervisor extension

rv_csr_t (page 78) **i**

bit: 8 RV32I/64I/128I base ISA

rv_csr_t (page 78) **j**

bit: 9 Tentatively reserved for Dynamically Translated Languages extension

rv_csr_t (page 78) **_reserved1**

bit: 10 Reserved

rv_csr_t (page 78) **l**

bit: 11 Tentatively reserved for Decimal Floating-Point extension

rv_csr_t (page 78) **m**

bit: 12 Integer Multiply/Divide extension

rv_csr_t (page 78) **n**

bit: 13 User-level interrupts supported

rv_csr_t (page 78) **_reserved2**

bit: 14 Reserved

rv_csr_t (page 78) **p**
 bit: 15 Tentatively reserved for Packed-SIMD extension

rv_csr_t (page 78) **q**
 bit: 16 Quad-precision floating-point extension

rv_csr_t (page 78) **_resreved3**
 bit: 17 Reserved

rv_csr_t (page 78) **s**
 bit: 18 Supervisor mode implemented

rv_csr_t (page 78) **t**
 bit: 19 Tentatively reserved for Transactional Memory extension

rv_csr_t (page 78) **u**
 bit: 20 User mode implemented

rv_csr_t (page 78) **v**
 bit: 21 Tentatively reserved for Vector extension

rv_csr_t (page 78) **_reserved4**
 bit: 22 Reserved

rv_csr_t (page 78) **x**
 bit: 23 Non-standard extensions present

rv_csr_t (page 78) **_reserved5**
 bit: 24..29 Reserved

rv_csr_t (page 78) **mx1**
 bit: 30..31 Machine XLEN

struct *CSR_MISA_Type* (page 78)::[anonymous] **b**
 Structure used for bit access.

union *CSR_MSTATUS_Type*
#include <core_feature_base.h> Union type to access MSTATUS configure register.

Public Members

rv_csr_t (page 78) **_reserved0**
 bit: 0 Reserved

rv_csr_t (page 78) **sie**
 bit: 1 supervisor interrupt enable flag

rv_csr_t (page 78) **_reserved1**
 bit: 2 Reserved

rv_csr_t (page 78) **mie**
 bit: 3 Machine mode interrupt enable flag

rv_csr_t (page 78) **_reserved2**
 bit: 4 Reserved

rv_csr_t (page 78) **spie**
 bit: 3 Supervisor Priviledge mode interrupt enable flag

rv_csr_t (page 78) **_reserved3**
 bit: Reserved

rv_csr_t (page 78) **mpie**
bit: mirror of MIE flag

rv_csr_t (page 78) **_reserved4**
bit: Reserved

rv_csr_t (page 78) **mpp**
bit: mirror of Privilege Mode

rv_csr_t (page 78) **fs**
bit: FS status flag

rv_csr_t (page 78) **xs**
bit: XS status flag

rv_csr_t (page 78) **mprv**
bit: Machine mode PMP

rv_csr_t (page 78) **sum**
bit: Supervisor Mode load and store protection

rv_csr_t (page 78) **_reserved6**
bit: 19..30 Reserved

rv_csr_t (page 78) **sd**
bit: Dirty status for XS or FS

struct *CSR_MSTATUS_Type* (page 79)::[anonymous] **b**
Structure used for bit access.

rv_csr_t (page 78) **d**
Type used for csr data access.

union *CSR_MTVEC_Type*
#include <core_feature_base.h> Union type to access MTVEC configure register.

Public Members

rv_csr_t (page 78) **mode**
bit: 0..5 interrupt mode control

rv_csr_t (page 78) **addr**
bit: 6..31 mtvec address

struct *CSR_MTVEC_Type* (page 80)::[anonymous] **b**
Structure used for bit access.

rv_csr_t (page 78) **d**
Type used for csr data access.

union *CSR_MCAUSE_Type*
#include <core_feature_base.h> Union type to access MCAUSE configure register.

Public Members

rv_csr_t (page 78) **exccode**
bit: 11..0 exception or interrupt code

rv_csr_t (page 78) **_reserved0**
bit: 15..12 Reserved

rv_csr_t (page 78) **mpil**
bit: 23..16 Previous interrupt level

rv_csr_t (page 78) **_reserved1**
bit: 26..24 Reserved

rv_csr_t (page 78) **mpie**
bit: 27 Interrupt enable flag before enter interrupt

rv_csr_t (page 78) **mpp**
bit: 29..28 Priviled mode flag before enter interrupt

rv_csr_t (page 78) **minhv**
bit: 30 Machine interrupt vector table

rv_csr_t (page 78) **interrupt**
bit: 31 trap type.

0 means exception and 1 means interrupt

struct *CSR_MCAUSE_Type* (page 80)::[anonymous] **b**
Structure used for bit access.

rv_csr_t (page 78) **d**
Type used for csr data access.

union **CSR_MCOUNTINHIBIT_Type**
#include <core_feature_base.h> Union type to access MCOUNTINHIBIT configure register.

Public Members

rv_csr_t (page 78) **cy**
bit: 0 1 means disable mcycle counter

#include <core_feature_base.h> Union type to access MSAVESTATUS configure register.

Public Members

rv_csr_t (page 78) **mpie1**
bit: 0 interrupt enable flag of first level NMI/exception nesting

rv_csr_t (page 78) **mpp1**
bit: 1..2 privilege mode of first level NMI/exception nesting

rv_csr_t (page 78) **_reserved0**
bit: 3..5 Reserved

rv_csr_t (page 78) **ptyp1**
bit: 6..7 NMI/exception type of before first nesting

rv_csr_t (page 78) **mpie2**
 bit: 8 interrupt enable flag of second level NMI/exception nestting

rv_csr_t (page 78) **mpp2**
 bit: 9..10 priviled mode of second level NMI/exception nestting

rv_csr_t (page 78) **__reserved1**
 bit: 11..13 Reserved

rv_csr_t (page 78) **ptyp2**
 bit: 14..15 NMI/exception type of before second nestting

rv_csr_t (page 78) **__reserved2**
 bit: 16..31 Reserved

struct *CSR_MSAVESTATUS_Type* (page 82)::[anonymous] **b**
 Structure used for bit access.

rv_csr_t (page 78) **w**
 Type used for csr data access.

ECLIC

group **NMSIS_Core_ECLIC_Registers**
 Type definitions and defines for eclic registers.

Defines

CLIC_CLICCFG_NLBIT_Pos 1U
 CLIC CLICCFG: NLBIT Position.

CLIC_CLICCFG_NLBIT_Msk (0xFUL << CLIC_CLICCFG_NLBIT_Pos)
 CLIC CLICCFG: NLBIT Mask.

CLIC_CLICINFO_CTLBIT_Pos 21U
 CLIC INTINFO: __ECLIC_GetInfoCtlbits() Position.

CLIC_CLICINFO_CTLBIT_Msk (0xFUL << CLIC_CLICINFO_CTLBIT_Pos)
 CLIC INTINFO: __ECLIC_GetInfoCtlbits() Mask.

CLIC_CLICINFO_VER_Pos 13U
 CLIC CLICINFO: VERSION Position.

CLIC_CLICINFO_VER_Msk (0xFFUL << CLIC_CLICCFG_NLBIT_Pos)
 CLIC CLICINFO: VERSION Mask.

CLIC_CLICINFO_NUM_Pos 0U
 CLIC CLICINFO: NUM Position.

CLIC_CLICINFO_NUM_Msk (0xFFFUL << CLIC_CLICINFO_NUM_Pos)
 CLIC CLICINFO: NUM Mask.

CLIC_INTIP_IP_Pos 0U
 CLIC INTIP: IP Position.

CLIC_INTIP_IP_Msk (0x1UL << CLIC_INTIP_IP_Pos)
 CLIC INTIP: IP Mask.

CLIC_INTIE_IE_Pos 0U
 CLIC INTIE: IE Position.

CLIC_INTIE_IE_Msk (0x1UL << CLIC_INTIE_IE_Pos)
CLIC INTIE: IE Mask.

CLIC_INTATTR_TRIG_Pos 1U
CLIC INTATTR: TRIG Position.

CLIC_INTATTR_TRIG_Msk (0x3UL << CLIC_INTATTR_TRIG_Pos)
CLIC INTATTR: TRIG Mask.

CLIC_INTATTR_SHV_Pos 0U
CLIC INTATTR: SHV Position.

CLIC_INTATTR_SHV_Msk (0x1UL << CLIC_INTATTR_SHV_Pos)
CLIC INTATTR: SHV Mask.

ECLIC_MAX_NLBITS 8U
Max nlbit of the CLICINTCTLBITS.

ECLIC_MODE_MTVEC_Msk 3U
ECLIC Mode mask for MTVT CSR Register.

ECLIC_NON_VECTOR_INTERRUPT 0x0
Non-Vector Interrupt Mode of ECLIC.

ECLIC_VECTOR_INTERRUPT 0x1
Vector Interrupt Mode of ECLIC.

ECLIC_BASE __ECLIC_BASEADDR
ECLIC Base Address.

ECLIC ((CLIC_Type *) [ECLIC_BASE](#) (page 84))
CLIC configuration struct.

Enums

enum ECLIC_TRIGGER_Type
ECLIC Trigger Enum for different Trigger Type.

Values:

ECLIC_LEVEL_TRIGGER = 0x0
Level Triggerred, trig[0] = 0.

ECLIC_POSTIVE_EDGE_TRIGGER = 0x1
Postive/Rising Edge Triggerred, trig[1] = 1, trig[0] = 0.

ECLIC_NEGTIVE_EDGE_TRIGGER = 0x3
Negtive/Falling Edge Triggerred, trig[1] = 1, trig[0] = 1.

ECLIC_MAX_TRIGGER = 0x3
MAX Supported Trigger Mode.

union CLICCFG_Type
#include <core_feature_eclic.h> Union type to access CLICCFG configure register.

Public Members

uint8_t _reserved0
bit: 0 Overflow condition code flag

```

uint8_t nlbits
    bit: 29 Carry condition code flag

uint8_t _reserved1
    bit: 30 Zero condition code flag

uint8_t _reserved2
    bit: 31 Negative condition code flag

struct CLICCFG_Type (page 84)::[anonymous] b
    Structure used for bit access.

uint8_t w
    Type used for byte access.

union CLICINFO_Type
    #include <core_feature_eclic.h> Union type to access CLICINFO information register.

```

Public Members

```

uint32_t numint
    bit: 0..12 number of maximum interrupt inputs supported

uint32_t version
    bit: 13..20 20:17 for architecture version,16:13 for implementation version

uint32_t intctlbits
    bit: 21..24 specifies how many hardware bits are actually implemented in the clicintctl registers

uint32_t _reserved0
    bit: 25..31 Reserved

struct CLICINFO_Type (page 85)::[anonymous] b
    Structure used for bit access.

uint32_t w
    Type used for word access.

struct CLIC_CTRL_Type
    #include <core_feature_eclic.h> Access to the structure of a vector interrupt controller.

```

SysTimer

group **NMSIS_Core_SysTimer_Registers**
Type definitions and defines for system timer registers.

Defines

```

SysTimer_MTIMECTL_TIMESTOP_Pos 0U
    SysTick Timer MTIMECTL: TIMESTOP bit Position.

SysTimer_MTIMECTL_TIMESTOP_Msk (1UL << SysTimer_MTIMECTL_TIMESTOP_Pos)
    SysTick Timer MTIMECTL: TIMESTOP Mask.

SysTimer_MTIMECTL_CMPCLREN_Pos 1U
    SysTick Timer MTIMECTL: CMPCLREN bit Position.

SysTimer_MTIMECTL_CMPCLREN_Msk (1UL << SysTimer_MTIMECTL_CMPCLREN_Pos)
    SysTick Timer MTIMECTL: CMPCLREN Mask.

```

SysTimer_MTIMECTL_CLKSRC_Pos 2U

SysTick Timer MTIMECTL: CLKSRC bit Position.

SysTimer_MTIMECTL_CLKSRC_Msk (1UL << SysTimer_MTIMECTL_CLKSRC_Pos)

SysTick Timer MTIMECTL: CLKSRC Mask.

SysTimer_MSIP_MSIP_Pos 0U

SysTick Timer MSIP: MSIP bit Position.

SysTimer_MSIP_MSIP_Msk (1UL << SysTimer_MSIP_MSIP_Pos)

SysTick Timer MSIP: MSIP Mask.

SysTimer_MTIMER_Msk (0xFFFFFFFFFFFFFFFFULL)

SysTick Timer MTIMER value Mask.

SysTimer_MTIMERCMP_Msk (0xFFFFFFFFFFFFFFFFULL)

SysTick Timer MTIMERCMP value Mask.

SysTimer_MTIMECTL_Msk (0xFFFFFFFFFUL)

SysTick Timer MTIMECTL/MSTOP value Mask.

SysTimer_MSIP_Msk (0xFFFFFFFFFUL)

SysTick Timer MSIP value Mask.

SysTimer_MSFRST_Msk (0xFFFFFFFFFUL)

SysTick Timer MSFRST value Mask.

SysTimer_MSFRST_KEY (0x80000A5FUL)

SysTick Timer Software Reset Request Key.

SysTimer_BASE __SYSTIMER_BASEADDR

SysTick Base Address.

SysTimer ((*SysTimer_Type* (page 86) *) *SysTimer_BASE* (page 86))

SysTick configuration struct.

struct SysTimer_Type

#include <core_feature_timer.h> Structure type to access the System Timer (SysTimer).

Structure definition to access the system timer(SysTimer).

Remark

- MSFRST register is introduced in Nuclei N Core version 1.3([__NUCLEI_N_REV](#) (page 58) >= 0x0103)
- MSTOP register is renamed to MTIMECTL register in Nuclei N Core version 1.4([__NUCLEI_N_REV](#) (page 58) >= 0x0104)
- CMPCLREN and CLKSRC bit in MTIMECTL register is introduced in Nuclei N Core version 1.4([__NUCLEI_N_REV](#) (page 58) >= 0x0104)

2.5.6 CPU Intrinsic Functions

enum NMSIS_Core_CPU_Intrinsic::WFI_SleepMode_Type

Values:

WFI_SHALLOW_SLEEP = 0

WFI_DEEP_SLEEP = 1

__CPU_RELAX() __ASM (page 59) volatile ("": : : "memory")

```

group **NMSIS_Core_CPU_Intrinsic**

Functions that generate RISC-V CPU instructions.

The following functions generate specified RISC-V instructions that cannot be directly accessed by compiler.

Defines

__FENCE (p, s) **__ASM** (page 59) volatile (“fence” #p “,” #s : : “memory”)

Execute fence instruction, p -> pred, s -> succ.

the FENCE instruction ensures that all memory accesses from instructions preceding the fence in program order (the predecessor set) appear earlier in the global memory order than memory accesses from instructions appearing after the fence in program order (the successor set). For details, please refer to The RISC-V Instruction Set Manual

Parameters

- p: predecessor set, such as iorw, rw, r, w
- s: successor set, such as iorw, rw, r, w

__RWMB () **__FENCE**(iorw,iorw)

Read & Write Memory barrier.

__RMB () **__FENCE**(ir,ir)

Read Memory barrier.

__WMB () **__FENCE**(ow,ow)

Write Memory barrier.

__SMP_RWMB () **__FENCE**(rw,rw)

SMP Read & Write Memory barrier.

__SMP_RMB () **__FENCE**(r,r)

SMP Read Memory barrier.

__SMP_WMB () **__FENCE**(w,w)

SMP Write Memory barrier.

__CPU_RELAX () **__ASM** (page 59) volatile (“” : : “memory”)

CPU relax for busy loop.

Enums

enum WFI_SleepMode_Type

WFI Sleep Mode enumeration.

Values:

WFI_SHALLOW_SLEEP = 0

Shallow sleep mode, the core_clk will poweroff.

WFI_DEEP_SLEEP = 1

Deep sleep mode, the core_clk and core_ano_clk will poweroff.

Functions

__STATIC_FORCEINLINE void __NOP(void)

NOP Instruction.

No Operation does nothing. This instruction can be used for code alignment purposes.

__STATIC_FORCEINLINE void __WFI(void)

Wait For Interrupt.

Wait For Interrupt is executed using CSR_WFE.WFE=0 and WFI instruction. It will suspend execution until interrupt, NMI or Debug happened. When Core is waked up by interrupt, if

1. mstatus.MIE == 1(interrupt enabled), Core will enter ISR code
2. mstatus.MIE == 0(interrupt disabled), Core will resume previous execution

__STATIC_FORCEINLINE void __WFE(void)

Wait For Event.

Wait For Event is executed using CSR_WFE.WFE=1 and WFI instruction. It will suspend execution until event, NMI or Debug happened. When Core is waked up, Core will resume previous execution

__STATIC_FORCEINLINE void __EBREAK(void)

Breakpoint Instruction.

Causes the processor to enter Debug state. Debug tools can use this to investigate system state when the instruction at a particular address is reached.

__STATIC_FORCEINLINE void __ECALL(void)

Environment Call Instruction.

The ECALL instruction is used to make a service request to the execution environment.

__STATIC_FORCEINLINE void __set_wfi_sleepmode(WFI_SleepMode_Type mode)

Set Sleep mode of WFI.

Set the SLEEPVALUE CSR register to control the WFI Sleep mode.

Parameters

- [in] mode: The sleep mode to be set

__STATIC_FORCEINLINE void __TXEVT(void)

Send TX Event.

Set the CSR TXEVT to control send a TX Event. The Core will output signal tx_evt as output event signal.

__STATIC_FORCEINLINE void __enable_mcycle_counter(void)

Enable MCYCLE counter.

Clear the CY bit of MCOUNTINHIBIT to 0 to enable MCYCLE Counter

__STATIC_FORCEINLINE void __disable_mcycle_counter(void)

Disable MCYCLE counter.

Set the CY bit of MCOUNTINHIBIT to 1 to disable MCYCLE Counter

__STATIC_FORCEINLINE void __enable_minstret_counter(void)

Enable MINSTRET counter.

Clear the IR bit of MCOUNTINHIBIT to 0 to enable MINSTRET Counter

__STATIC_FORCEINLINE void __disable_minstret_counter(void)

Disable MINSTRET counter.

Set the IR bit of MCOUNTINHIBIT to 1 to disable MINSTRET Counter

__STATIC_FORCEINLINE void __enable_all_counter(void)

Enable MCYCLE & MINSTRET counter.

Clear the IR and CY bit of MCOUNTINHIBIT to 1 to enable MINSTRET & MCYCLE Counter

__STATIC_FORCEINLINE void __disable_all_counter(void)
Disable MCYCLE & MINSTRET counter.
Set the IR and CY bit of MCOUNTINHIBIT to 1 to disable MINSTRET & MCYCLE Counter

__STATIC_FORCEINLINE void __FENCE_I(void)
Fence.i Instruction.
The FENCE.I instruction is used to synchronize the instruction and data streams.

__STATIC_FORCEINLINE uint8_t __LB(volatile void * addr)
Load 8bit value from address (8 bit)
Load 8 bit value.
Return value of type uint8_t at (*addr)
Parameters

- [in] addr: Address pointer to data

__STATIC_FORCEINLINE uint16_t __LH(volatile void * addr)
Load 16bit value from address (16 bit)
Load 16 bit value.
Return value of type uint16_t at (*addr)
Parameters

- [in] addr: Address pointer to data

__STATIC_FORCEINLINE uint32_t __LW(volatile void * addr)
Load 32bit value from address (32 bit)
Load 32 bit value.
Return value of type uint32_t at (*addr)
Parameters

- [in] addr: Address pointer to data

__STATIC_FORCEINLINE void __SB(volatile void * addr, uint8_t val)
Write 8bit value to address (8 bit)
Write 8 bit value.
Parameters

- [in] addr: Address pointer to data
- [in] val: Value to set

__STATIC_FORCEINLINE void __SH(volatile void * addr, uint16_t val)
Write 16bit value to address (16 bit)
Write 16 bit value.
Parameters

- [in] addr: Address pointer to data
- [in] val: Value to set

__STATIC_FORCEINLINE void __SW(volatile void * addr, uint32_t val)
Write 32bit value to address (32 bit)
Write 32 bit value.

Parameters

- [in] addr: Address pointer to data
- [in] val: Value to set

__STATIC_FORCEINLINE uint32_t __CAS_W(volatile uint32_t * addr, uint32_t oldval, uint32_t newval)

Compare and Swap 32bit value using LR and SC.

Compare old value with memory, if identical, store new value in memory. Return the initial value in memory. Success is indicated by comparing return value with OLD. memory address, return 0 if successful, otherwise return !0

Return return the initial value in memory

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] oldval: Old value of the data in address
- [in] newval: New value to be stored into the address

__STATIC_FORCEINLINE uint32_t __AMOSWAP_W(volatile uint32_t * addr, uint32_t newval)

Atomic Swap 32bit value into memory.

Atomically swap new 32bit value into memory using amoswap.d.

Return return the original value in memory

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] newval: New value to be stored into the address

__STATIC_FORCEINLINE int32_t __AMOADD_W(volatile int32_t * addr, int32_t value)

Atomic Add with 32bit value.

Atomically ADD 32bit value with value in memory using amoadd.d.

Return return memory value + add value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be ADDED

__STATIC_FORCEINLINE int32_t __AMOAND_W(volatile int32_t * addr, int32_t value)

Atomic And with 32bit value.

Atomically AND 32bit value with value in memory using amoand.d.

Return return memory value & and value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be ANDed

__STATIC_FORCEINLINE int32_t __AMOOR_W(volatile int32_t * addr, int32_t value)

Atomic OR with 32bit value.

Atomically OR 32bit value with value in memory using amoor.d.

Return return memory value | and value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be ORed

__STATIC_FORCEINLINE int32_t __AMOXOR_W(volatile int32_t * addr, int32_t value)
Atomic XOR with 32bit value.

Atomically XOR 32bit value with value in memory using amoxor.d.

Return return memory value ^ and value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be XORed

__STATIC_FORCEINLINE uint32_t __AMOMAXU_W(volatile uint32_t * addr, uint32_t value)
Atomic unsigned MAX with 32bit value.

Atomically unsigned max compare 32bit value with value in memory using amomaxu.d.

Return return the bigger value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be compared

__STATIC_FORCEINLINE int32_t __AMOMAX_W(volatile int32_t * addr, int32_t value)
Atomic signed MAX with 32bit value.

Atomically signed max compare 32bit value with value in memory using amomax.d.

Return the bigger value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be compared

__STATIC_FORCEINLINE uint32_t __AMOMINU_W(volatile uint32_t * addr, uint32_t value)
Atomic unsigned MIN with 32bit value.

Atomically unsigned min compare 32bit value with value in memory using amominu.d.

Return the smaller value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be compared

__STATIC_FORCEINLINE int32_t __AMOMIN_W(volatile int32_t * addr, int32_t value)
Atomic signed MIN with 32bit value.

Atomically signed min compare 32bit value with value in memory using amomin.d.

Return the smaller value

Parameters

- [in] addr: Address pointer to data, address need to be 4byte aligned
- [in] value: value to be compared

SIMD 16-bit Add/Subtract Instructions.

Based on the combination of the types of the two 16-bit arithmetic operations, the SIMD 16-bit add/subtract instructions can be classified into 6 main categories: Addition (two 16-bit addition), Subtraction (two 16-bit subtraction), Crossed Add & Sub (one addition and one subtraction), and Crossed Sub & Add (one subtraction and one addition), Straight Add & Sub (one addition and one subtraction), and Straight Sub & Add (one subtraction and one addition). Based on the way of how an overflow condition is handled, the SIMD 16-bit add/subtract instructions can be classified into 5 groups: Wrap-around (dropping overflow), Signed Halving (keeping overflow by dropping 1 LSB bit), Unsigned Halving, Signed Saturation (clipping overflow), and Unsigned Saturation. Together, there are 30 SIMD 16-bit add/subtract instructions.

Functions

```
__STATIC_FORCEINLINE unsigned long __RV_ADD16(unsigned long a, unsigned long b)
```

ADD16 (SIMD 16-bit Addition)

Type: SIMD

Syntax:

```
ADD16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit integer element additions simultaneously.

Description: This instruction adds the 16-bit integer elements in Rs1 with the 16-bit integer elements in Rs2, and then writes the 16-bit element results to Rd.

Note: This instruction can be used for either signed or unsigned addition.

Operations:

```
Rd.H[x] = Rs1.H[x] + Rs2.H[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_CRAS16(unsigned long a, unsigned long b)
```

CRAS16 (SIMD 16-bit Cross Addition & Subtraction)

Type: SIMD

Syntax:

```
CRAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit integer element addition and 16-bit integer element subtraction in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks.

Description: This instruction adds the 16-bit integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit integer element in [15:0] of 32-bit chunks in Rs2, and writes the result to [31:16] of 32-bit chunks

in Rd; at the same time, it subtracts the 16-bit integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit integer element in [15:0] of 32-bit chunks, and writes the result to [15:0] of 32-bit chunks in Rd.

Note: This instruction can be used for either signed or unsigned operations.

Operations:

```
Rd.W[x][31:16] = Rs1.W[x][31:16] + Rs2.W[x][15:0];
Rd.W[x][15:0] = Rs1.W[x][15:0] - Rs2.W[x][31:16];
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_CRSA16(unsigned long a, unsigned long b)
CRSA16 (SIMD 16-bit Cross Subtraction & Addition)

Type: SIMD

Syntax:

```
CRSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit integer element subtraction and 16-bit integer element addition in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks.

Description: This instruction subtracts the 16-bit integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit integer element in [31:16] of 32-bit chunks in Rs1, and writes the result to [31:16] of 32-bit chunks in Rd; at the same time, it adds the 16-bit integer element in [31:16] of 32-bit chunks in Rs2 with the 16-bit integer element in [15:0] of 32-bit chunks in Rs1, and writes the result to [15:0] of 32-bit chunks in Rd.

Note: This instruction can be used for either signed or unsigned operations.

Operations:

```
Rd.W[x][31:16] = Rs1.W[x][31:16] - Rs2.W[x][15:0];
Rd.W[x][15:0] = Rs1.W[x][15:0] + Rs2.W[x][31:16];
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KADD16(unsigned long a, unsigned long b)
KADD16 (SIMD 16-bit Signed Saturating Addition)

Type: SIMD

Syntax:

```
KADD16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element saturating additions simultaneously.

Description: This instruction adds the 16-bit signed integer elements in Rs1 with the 16-bit signed integer elements in Rs2. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.H[x] + Rs2.H[x];
if (res[x] > 32767) {
    res[x] = 32767;
    OV = 1;
} else if (res[x] < -32768) {
    res[x] = -32768;
    OV = 1;
}
Rd.H[x] = res[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KCRAS16(unsigned long a, unsigned long b)
KCRAS16 (SIMD 16-bit Signed Saturating Cross Addition & Subtraction)

Type: SIMD

Syntax:

```
KCRAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element saturating addition and 16-bit signed integer element saturating subtraction in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks.

Description: This instruction adds the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2; at the same time, it subtracts the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for addition and [15:0] of 32-bit chunks in Rd for subtraction.

Operations:

```
res1 = Rs1.W[x][31:16] + Rs2.W[x][15:0];
res2 = Rs1.W[x][15:0] - Rs2.W[x][31:16];
for (res in [res1, res2]) {
    if (res > (2^15)-1) {
        res = (2^15)-1;
        OV = 1;
    } else if (res < -2^15) {
        res = -2^15;
    }
}
```

(continues on next page)

(continued from previous page)

```

    OV = 1;
}
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KCRSA16(unsigned long a, unsigned long b)
KCRSA16 (SIMD 16-bit Signed Saturating Cross Subtraction & Addition)

Type: SIMD

Syntax:

```
KCRSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element saturating subtraction and 16-bit signed integer element saturating addition in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks.

Description: This instruction subtracts the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1; at the same time, it adds the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2 with the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for subtraction and [15:0] of 32-bit chunks in Rd for addition.

Operations:

```

res1 = Rs1.W[x][31:16] - Rs2.W[x][15:0];
res2 = Rs1.W[x][15:0] + Rs2.W[x][31:16];
for (res in [res1, res2]) {
    if (res > (2^15)-1) {
        res = (2^15)-1;
        OV = 1;
    } else if (res < -2^15) {
        res = -2^15;
        OV = 1;
    }
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KSTAS16(unsigned long a, unsigned long b)
KSTAS16 (SIMD 16-bit Signed Saturating Straight Addition & Subtraction)

Type: SIMD

Syntax:

```
KSTAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element saturating addition and 16-bit signed integer element saturating subtraction in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks.

Description: This instruction adds the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2; at the same time, it subtracts the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for addition and [15:0] of 32-bit chunks in Rd for subtraction.

Operations:

```
res1 = Rs1.W[x][31:16] + Rs2.W[x][31:16];
res2 = Rs1.W[x][15:0] - Rs2.W[x][15:0];
for (res in [res1, res2]) {
    if (res > (2^15)-1) {
        res = (2^15)-1;
        OV = 1;
    } else if (res < -2^15) {
        res = -2^15;
        OV = 1;
    }
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KTSA16(unsigned long a, unsigned long b)
KTSA16 (SIMD 16-bit Signed Saturating Straight Subtraction & Addition)

Type: SIMD

Syntax:

```
KTSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element saturating subtraction and 16-bit signed integer element saturating addition in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks.

Description: This instruction subtracts the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1; at the same time, it adds

the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2 with the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for subtraction and [15:0] of 32-bit chunks in Rd for addition.

Operations:

```
res1 = Rs1.W[x][31:16] - Rs2.W[x][31:16];
res2 = Rs1.W[x][15:0] + Rs2.W[x][15:0];
for (res in [res1, res2]) {
    if (res > (2^15)-1) {
        res = (2^15)-1;
        OV = 1;
    } else if (res < -2^15) {
        res = -2^15;
        OV = 1;
    }
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KSUB16(unsigned long a, unsigned long b)
KSUB16 (SIMD 16-bit Signed Saturating Subtraction)

Type: SIMD

Syntax:

```
KSUB16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer elements saturating subtractions simultaneously.

Description: This instruction subtracts the 16-bit signed integer elements in Rs2 from the 16-bit signed integer elements in Rs1. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.H[x] - Rs2.H[x];
if (res[x] > (2^15)-1) {
    res[x] = (2^15)-1;
    OV = 1;
} else if (res[x] < -2^15) {
    res[x] = -2^15;
    OV = 1;
}
Rd.H[x] = res[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RADD16(unsigned long a, unsigned long b)
RADD16 (SIMD 16-bit Signed Halving Addition)

Type: SIMD

Syntax:

`RADD16 Rd, Rs1, Rs2`

Purpose: Do 16-bit signed integer element additions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 16-bit signed integer elements in Rs1 with the 16-bit signed integer elements in Rs2. The results are first arithmetically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Rs1 = 0x7FFF, Rs2 = 0x7FFF, Rd = 0x7FFF
* Rs1 = 0x8000, Rs2 = 0x8000, Rd = 0x8000
* Rs1 = 0x4000, Rs2 = 0x8000, Rd = 0xE000
```

Operations:

`Rd.H[x] = (Rs1.H[x] + Rs2.H[x]) s>> 1; for RV32: x=1...0, for RV64: x=3...0`

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RCRAS16(unsigned long a, unsigned long b)
RCRAS16 (SIMD 16-bit Signed Halving Cross Addition & Subtraction)

Type: SIMD

Syntax:

`RCRAS16 Rd, Rs1, Rs2`

Purpose: Do 16-bit signed integer element addition and 16-bit signed integer element subtraction in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2, and subtracts the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1. The element results are first arithmetically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

Please see `RADD16` and `RSUB16` instructions.

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] + Rs2.W[x][15:0]) s>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] - Rs2.W[x][31:16]) s>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RCRSA16(unsigned long a, unsigned long b)
RCRSA16 (SIMD 16-bit Signed Halving Cross Subtraction & Addition)

Type: SIMD

Syntax:

RCRSA16 Rd, Rs1, Rs2

Purpose: Do 16-bit signed integer element subtraction and 16-bit signed integer element addition in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1, and adds the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1 with the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2. The two results are first arithmetically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

Please see `RADD16` and `RSUB16` instructions.

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] - Rs2.W[x][15:0]) s>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] + Rs2.W[x][31:16]) s>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RSTAS16(unsigned long a, unsigned long b)
RSTAS16 (SIMD 16-bit Signed Halving Straight Addition & Subtraction)

Type: SIMD

Syntax:

```
RSTAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element addition and 16-bit signed integer element subtraction in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2, and subtracts the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1. The element results are first arithmetically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

```
Please see `RADD16` and `RSUB16` instructions.
```

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] + Rs2.W[x][31:16]) s>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] - Rs2.W[x][15:0]) s>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_RSTSA16(unsigned long a, unsigned long b)
RSTSA16 (SIMD 16-bit Signed Halving Straight Subtraction & Addition)
```

Type: SIMD

Syntax:

```
RSTSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element subtraction and 16-bit signed integer element addition in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit signed integer element in [31:16] of 32-bit chunks in Rs1, and adds the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs1 with the 16-bit signed integer element in [15:0] of 32-bit chunks in Rs2. The two results are first arithmetically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

```
Please see `RADD16` and `RSUB16` instructions.
```

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] - Rs2.W[x][31:16]) s>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] + Rs2.W[x][15:0]) s>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RSUB16(unsigned long a, unsigned long b)
RSUB16 (SIMD 16-bit Signed Halving Subtraction)

Type: SIMD

Syntax:

```
RSUB16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer element subtractions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 16-bit signed integer elements in Rs2 from the 16-bit signed integer elements in Rs1. The results are first arithmetically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Ra = 0x7FFF, Rb = 0x8000, Rt = 0x7FFF
* Ra = 0x8000, Rb = 0x7FFF, Rt = 0x8000
* Ra = 0x8000, Rb = 0x4000, Rt = 0xA000
```

Operations:

```
Rd.H[x] = (Rs1.H[x] - Rs2.H[x]) s>> 1;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_STAS16(unsigned long a, unsigned long b)
STAS16 (SIMD 16-bit Straight Addition & Subtraction)

Type: SIMD

Syntax:

```
STAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit integer element addition and 16-bit integer element subtraction in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks.

Description: This instruction adds the 16-bit integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit integer element in [31:16] of 32-bit chunks in Rs2, and writes the result to [31:16] of 32-bit chunks in Rd; at the same time, it subtracts the 16-bit integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit integer element in [15:0] of 32-bit chunks, and writes the result to [15:0] of 32-bit chunks in Rd.

Note: This instruction can be used for either signed or unsigned operations.

Operations:

```

Rd.W[x][31:16] = Rs1.W[x][31:16] + Rs2.W[x][31:16];
Rd.W[x][15:0] = Rs1.W[x][15:0] - Rs2.W[x][15:0];
for RV32, x=0
for RV64, x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_STSA16(unsigned long a, unsigned long b)
STSA16 (SIMD 16-bit Straight Subtraction & Addition)

Type: SIMD

Syntax:

```
STSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit integer element subtraction and 16-bit integer element addition in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks.

Description: This instruction subtracts the 16-bit integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit integer element in [31:16] of 32-bit chunks in Rs1, and writes the result to [31:16] of 32-bit chunks in Rd; at the same time, it adds the 16-bit integer element in [15:0] of 32-bit chunks in Rs2 with the 16-bit integer element in [15:0] of 32-bit chunks in Rs1, and writes the result to [15:0] of 32-bit chunks in Rd.

Note: This instruction can be used for either signed or unsigned operations.

Operations:

```

Rd.W[x][31:16] = Rs1.W[x][31:16] - Rs2.W[x][31:16];
Rd.W[x][15:0] = Rs1.W[x][15:0] + Rs2.W[x][15:0];
for RV32, x=0
for RV64, x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_SUB16(unsigned long a, unsigned long b)
SUB16 (SIMD 16-bit Subtraction)

Type: SIMD

Syntax:

```
SUB16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit integer element subtractions simultaneously.

Description: This instruction subtracts the 16-bit integer elements in Rs2 from the 16-bit integer elements in Rs1, and then writes the result to Rd.

Note: This instruction can be used for either signed or unsigned subtraction.

Operations:

```
Rd.H[x] = Rs1.H[x] - Rs2.H[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKADD16(unsigned long a, unsigned long b)
UKADD16 (SIMD 16-bit Unsigned Saturating Addition)

Type: SIMD

Syntax:

```
UKADD16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer element saturating additions simultaneously.

Description: This instruction adds the 16-bit unsigned integer elements in Rs1 with the 16-bit unsigned integer elements in Rs2. If any of the results are beyond the 16-bit unsigned number range ($0 \leq \text{RES} \leq 2^{16}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.H[x] + Rs2.H[x];
if (res[x] > (2^16)-1) {
    res[x] = (2^16)-1;
    OV = 1;
}
Rd.H[x] = res[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKCRAS16(unsigned long a, unsigned long b)
UKCRAS16 (SIMD 16-bit Unsigned Saturating Cross Addition & Subtraction)

Type: SIMD

Syntax:

```
UKCRAS16 Rd, Rs1, Rs2
```

Purpose: Do one 16-bit unsigned integer element saturating addition and one 16-bit unsigned integer element saturating subtraction in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks.

Description: This instruction adds the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs2; at the same time, it subtracts the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the 16-bit unsigned number range ($0 \leq \text{RES} \leq 2^{16}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for addition and [15:0] of 32-bit chunks in Rd for subtraction.

Operations:

```
res1 = Rs1.W[x][31:16] + Rs2.W[x][15:0];
res2 = Rs1.W[x][15:0] - Rs2.W[x][31:16];
if (res1 > (2^16)-1) {
    res1 = (2^16)-1;
    OV = 1;
}
if (res2 < 0) {
    res2 = 0;
    OV = 1;
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKCRSA16(unsigned long a, unsigned long b)
UKCRSA16 (SIMD 16-bit Unsigned Saturating Cross Subtraction & Addition)

Type: SIMD

Syntax:

```
UKCRSA16 Rd, Rs1, Rs2
```

Purpose: Do one 16-bit unsigned integer element saturating subtraction and one 16-bit unsigned integer element saturating addition in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks.

Description: This instruction subtracts the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs1; at the same time, it adds the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs2 with the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the 16-bit unsigned number range ($0 \leq \text{RES} \leq 2^{16}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for subtraction and [15:0] of 32-bit chunks in Rd for addition.

Operations:

```
res1 = Rs1.W[x][31:16] - Rs2.W[x][15:0];
res2 = Rs1.W[x][15:0] + Rs2.W[x][31:16];
if (res1 < 0) {
    res1 = 0;
}
```

(continues on next page)

(continued from previous page)

```

    OV = 1;
} else if (res2 > (2^16)-1) {
    res2 = (2^16)-1;
    OV = 1;
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKSTAS16(unsigned long a, unsigned long b)
UKSTAS16 (SIMD 16-bit Unsigned Saturating Straight Addition & Subtraction)

Type: SIMD

Syntax:

```
UKSTAS16 Rd, Rs1, Rs2
```

Purpose: Do one 16-bit unsigned integer element saturating addition and one 16-bit unsigned integer element saturating subtraction in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks.

Description: This instruction adds the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs1 with the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs2; at the same time, it subtracts the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs2 from the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the 16-bit unsigned number range ($0 \leq \text{RES} \leq 2^{16}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for addition and [15:0] of 32-bit chunks in Rd for subtraction.

Operations:

```

res1 = Rs1.W[x][31:16] + Rs2.W[x][31:16];
res2 = Rs1.W[x][15:0] - Rs2.W[x][15:0];
if (res1 > (2^16)-1) {
    res1 = (2^16)-1;
    OV = 1;
}
if (res2 < 0) {
    res2 = 0;
    OV = 1;
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKSTSA16(unsigned long a, unsigned long b)
UKSTSA16 (SIMD 16-bit Unsigned Saturating Straight Subtraction & Addition)

Type: SIMD

Syntax:

```
UKSTSA16 Rd, Rs1, Rs2
```

Purpose: Do one 16-bit unsigned integer element saturating subtraction and one 16-bit unsigned integer element saturating addition in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks.

Description: This instruction subtracts the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs2 from the 16-bit unsigned integer element in [31:16] of 32-bit chunks in Rs1; at the same time, it adds the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs2 with the 16-bit unsigned integer element in [15:0] of 32-bit chunks in Rs1. If any of the results are beyond the 16-bit unsigned number range ($0 \leq \text{RES} \leq 2^{16}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to [31:16] of 32-bit chunks in Rd for subtraction and [15:0] of 32-bit chunks in Rd for addition.

Operations:

```
res1 = Rs1.W[x][31:16] - Rs2.W[x][31:16];
res2 = Rs1.W[x][15:0] + Rs2.W[x][15:0];
if (res1 < 0) {
    res1 = 0;
    OV = 1;
} else if (res2 > (2^16)-1) {
    res2 = (2^16)-1;
    OV = 1;
}
Rd.W[x][31:16] = res1;
Rd.W[x][15:0] = res2;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKSUB16(unsigned long a, unsigned long b)
UKSUB16 (SIMD 16-bit Unsigned Saturating Subtraction)

Type: SIMD

Syntax:

```
UKSUB16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer elements saturating subtractions simultaneously.

Description: This instruction subtracts the 16-bit unsigned integer elements in Rs2 from the 16-bit unsigned integer elements in Rs1. If any of the results are beyond the 16-bit unsigned number range ($0 \leq$

RES $\leq 2^{16}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.H[x] - Rs2.H[x];
if (res[x] < 0) {
    res[x] = 0;
    OV = 1;
}
Rd.H[x] = res[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URADD16(unsigned long a, unsigned long b)
URADD16 (SIMD 16-bit Unsigned Halving Addition)

Type: SIMD

Syntax:

```
URADD16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer element additions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 16-bit unsigned integer elements in Rs1 with the 16-bit unsigned integer elements in Rs2. The results are first logically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Ra = 0x7FFF, Rb = 0x7FFF Rt = 0x7FFF
* Ra = 0x8000, Rb = 0x8000 Rt = 0x8000
* Ra = 0x4000, Rb = 0x8000 Rt = 0x6000
```

Operations:

```
Rd.H[x] = (Rs1.H[x] + Rs2.H[x]) u>> 1;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URCRAS16(unsigned long a, unsigned long b)
URCRAS16 (SIMD 16-bit Unsigned Halving Cross Addition & Subtraction)

Type: SIMD

Syntax:

```
URCRAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer element addition and 16-bit unsigned integer element subtraction in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs1 with the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs2, and subtracts the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs2 from the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs1. The element results are first logically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

```
Please see `URADD16` and `URSUB16` instructions.
```

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] + Rs2.W[x][15:0]) u>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] - Rs2.W[x][31:16]) u>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_URCRSA16(unsigned long a, unsigned long b)
URCRSA16 (SIMD 16-bit Unsigned Halving Cross Subtraction & Addition)
```

Type: SIMD

Syntax:

```
URCRSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer element subtraction and 16-bit unsigned integer element addition in a 32-bit chunk simultaneously. Operands are from crossed positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs2 from the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs1, and adds the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs1 with the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs2. The two results are first logically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

```
Please see `URADD16` and `URSUB16` instructions.
```

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] - Rs2.W[x][15:0]) u>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] + Rs2.W[x][31:16]) u>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URSTAS16(unsigned long a, unsigned long b)
URSTAS16 (SIMD 16-bit Unsigned Halving Straight Addition & Subtraction)

Type: SIMD

Syntax:

```
URSTAS16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer element addition and 16-bit unsigned integer element subtraction in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs1 with the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs2, and subtracts the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs2 from the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs1. The element results are first logically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

```
Please see `URADD16` and `URSUB16` instructions.
```

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] + Rs2.W[x][31:16]) u>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] - Rs2.W[x][15:0]) u>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URSTSA16(unsigned long a, unsigned long b)
URSTSA16 (SIMD 16-bit Unsigned Halving Straight Subtraction & Addition)

Type: SIMD

Syntax:

```
URCRSA16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer element subtraction and 16-bit unsigned integer element addition in a 32-bit chunk simultaneously. Operands are from corresponding positions in 32-bit chunks. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs2 from the 16-bit unsigned integer in [31:16] of 32-bit chunks in Rs1, and adds the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs1 with the 16-bit unsigned integer in [15:0] of 32-bit chunks in Rs2. The two

results are first logically right-shifted by 1 bit and then written to [31:16] of 32-bit chunks in Rd and [15:0] of 32-bit chunks in Rd.

Examples:

Please see `URADD16` and `URSUB16` instructions.

Operations:

```
Rd.W[x][31:16] = (Rs1.W[x][31:16] - Rs2.W[x][31:16]) u>> 1;
Rd.W[x][15:0] = (Rs1.W[x][15:0] + Rs2.W[x][15:0]) u>> 1;
for RV32, x=0
for RV64, x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URSUB16(unsigned long a, unsigned long b)
 URSUB16 (SIMD 16-bit Unsigned Halving Subtraction)

Type: SIMD

Syntax:

URSUB16 Rd, Rs1, Rs2

Purpose: Do 16-bit unsigned integer element subtractions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 16-bit unsigned integer elements in Rs2 from the 16-bit unsigned integer elements in Rs1. The results are first logically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Ra = 0x7FFF, Rb = 0x8000 Rt = 0xFFFF

there are 14 SIMD 16-bit shift instructions.

Defines

__RV_KSLLI16 (a, b)
KSLLI16 (SIMD 16-bit Saturating Shift Left Logical Immediate)

Type: SIMD

Syntax:

```
KSLLI16 Rd, Rs1, imm4u
```

Purpose: Do 16-bit elements logical left shift operations with saturation simultaneously. The shift amount is an immediate value.

Description: The 16-bit data elements in Rs1 are left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the imm4u constant. Any shifted value greater than $2^{15}-1$ is saturated to $2^{15}-1$. Any shifted value smaller than -2^{15} is saturated to -2^{15} . And the saturated results are written to Rd. If any saturation is performed, set OV bit to 1.

Operations:

```

sa = imm4u[3:0];
if (sa != 0) {
    res[(15+sa):0] = Rs1.H[x] << sa;
    if (res > (2^15)-1) {
        res = 0x7fff; OV = 1;
    } else if (res < -2^15) {
        res = 0x8000; OV = 1;
    }
}

```

(continues on next page)

(continued from previous page)

```

    }
    Rd.H[x] = res[15:0];
} else {
    Rd = Rs1;
}
for RV32: x=1...0,
for RV64: x=3...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__RV_SLLI16 (a, b)

SLLI16 (SIMD 16-bit Shift Left Logical Immediate)

Type: SIMD

Syntax:

```
SLLI16 Rd, Rs1, imm4[3:0]
```

Purpose: Do 16-bit element logical left shift operations simultaneously. The shift amount is an immediate value.

Description: The 16-bit elements in Rs1 are left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the imm4[3:0] constant. And the results are written to Rd.

Operations:

```

sa = imm4[3:0];
Rd.H[x] = Rs1.H[x] << sa;
for RV32: x=1...0,
for RV64: x=3...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__RV_SRAI16 (a, b)

SRAI16 (SIMD 16-bit Shift Right Arithmetic Immediate)

Type: SIMD

Syntax:

```

SRAI16 Rd, Rs1, imm4u
SRAI16.u Rd, Rs1, imm4u

```

Purpose: Do 16-bit elements arithmetic right shift operations simultaneously. The shift amount is an immediate value. The .u form performs additional rounding up operations on the shifted results.

Description: The 16-bit data elements in Rs1 are right-shifted arithmetically, that is, the shifted out bits are filled with the sign-bit of the 16-bit data elements. The shift amount is specified by the imm4u constant. For the rounding operation of the .u form, a value of 1 is added to the most significant discarded bit of each 16-bit data to calculate the final results. And the results are written to Rd.

Operations:

```
sa = imm4u[3:0];
if (sa > 0) {
    if (`.u` form) { // SRAI16.u
        res[15:-1] = SE17(Rs1.H[x][15:sa-1]) + 1;
        Rd.H[x] = res[15:0];
    } else { // SRAI16

`__STATIC_FORCEINLINE unsigned long __RV_KSLL16(unsigned long a, unsigned int b)`
KSLL16 (SIMD 16-bit Saturating Shift Left Logical)

Type: SIMD

Syntax:

```
KSLL16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit elements logical left shift operations with saturation simultaneously. The shift amount is a variable from a GPR.

Description: The 16-bit data elements in Rs1 are left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the low-order 4-bits of the value in the Rs2 register. Any shifted value greater than $2^{15}-1$ is saturated to $2^{15}-1$. Any shifted value smaller than -2^{15} is saturated to -2^{15} . And the saturated results are written to Rd. If any saturation is performed, set OV bit to 1.

Operations:

```

sa = Rs2[3:0];
if (sa != 0) {
    res[(15+sa):0] = Rs1.H[x] << sa;
    if (res > (2^15)-1) {
        res = 0x7fff; OV = 1;
    } else if (res < -2^15) {
        res = 0x8000; OV = 1;
    }
    Rd.H[x] = res[15:0];
} else {
    Rd = Rs1;
}
for RV32: x=1...0,
for RV64: x=3...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KSLRA16(unsigned long a, int b)
 KSLRA16 (SIMD 16-bit Shift Left Logical with Saturation or Shift Right Arithmetic)

Type: SIMD

Syntax:

```

KSLRA16 Rd, Rs1, Rs2
KSLRA16.u Rd, Rs1, Rs2

```

Purpose: Do 16-bit elements logical left (positive) or arithmetic right (negative) shift operation with Q15 saturation for the left shift. The .u form performs additional rounding up operations for the right shift.

Description: The 16-bit data elements of Rs1 are left-shifted logically or right-shifted arithmetically based on the value of Rs2[4:0]. Rs2[4:0] is in the signed range of $[-2^4, 2^4-1]$. A positive Rs2[4:0] means logical left shift and a negative Rs2[4:0] means arithmetic right shift. The shift amount is the absolute value of Rs2[4:0]. However, the behavior of $Rs2[4:0] == -2^4$ (0x10) is defined to be equivalent to the behavior of $Rs2[4:0] == -(2^4-1)$ (0x11). The left-shifted results are saturated to the 16-bit signed integer range of $[-2^{15}, 2^{15}-1]$. For the .u form of the instruction, the right-shifted results are added a 1 to the most significant discarded bit position for rounding effect. After the shift, saturation, or rounding, the final results are written to Rd. If any saturation happens, this instruction sets the OV flag. The value of Rs2[31:5] will not affect this instruction.

Operations:

```

if (Rs2[4:0] < 0) {
    sa = -Rs2[4:0];
    sa = (sa == 16)? 15 : sa;
    if (`.u` form) {
        res[15:-1] = SE17(Rs1.H[x][15:sa-1]) + 1;
        Rd.H[x] = res[15:0];
    } else {
        Rd.H[x] = SE16(Rs1.H[x][15:sa]);
    }
} else {
    sa = Rs2[3:0];

```

(continues on next page)

(continued from previous page)

```

    res[(15+sa):0] = Rs1.H[x] <<(logic) sa;
    if (res > (2^15)-1) {
        res[15:0] = 0x7fff; OV = 1;
    } else if (res < -2^15) {
        res[15:0] = 0x8000; OV = 1;
    }
    d.H[x] = res[15:0];
}
for RV32: x=1...0,
for RV64: x=3...0

```

Return value stored in unsigned long type

KSLLI8 (SIMD 8-bit Saturating Shift Left Logical Immediate)

Type: SIMD

Syntax:

```
KSLLI8 Rd, Rs1, imm3u
```

Purpose: Do 8-bit elements logical left shift operations with saturation simultaneously. The shift amount is an immediate value.

Description: The 8-bit data elements in Rs1 are left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the imm3u constant. Any shifted value greater than 2^7-1 is saturated to 2^7-1 . Any shifted value smaller than -2^7 is saturated to -2^7 . And the saturated results are written to Rd. If any saturation is performed, set OV bit to 1.

Operations:

```
sa = imm3u[2:0];
if (sa != 0) {
    res[(7+sa):0] = Rs1.B[x] << sa;
    if (res > (2^7)-1) {
        res = 0x7f; OV = 1;
    } else if (res < -2^7) {
        res = 0x80; OV = 1;
    }
    Rd.B[x] = res[7:0];
} else {
    Rd = Rs1;
}
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

`__RV_SLLI8` (a, b)

SLLI8 (SIMD 8-bit Shift Left Logical Immediate)

Type: SIMD

Syntax:

```
SLLI8 Rd, Rs1, imm3u
```

Purpose: Do 8-bit elements logical left shift operations simultaneously. The shift amount is an immediate value.

Description: The 8-bit elements in Rs1 are left-shifted logically. And the results are written to Rd. The shifted out bits are filled with zero and the shift amount is specified by the imm3u constant.

Operations:

```
sa = imm3u[2:0];
Rd.B[x] = Rs1.B[x] << sa;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__RV_SRAI8 (a, b)
SRAI8 (SIMD 8-bit Shift Right Arithmetic Immediate)

Type: SIMD

Syntax:

```
SRAI8 Rd, Rs1, imm3u
SRAI8.u Rd, Rs1, imm3u
```

Purpose: Do 8-bit element arithmetic right shift operations simultaneously. The shift amount is an immediate value. The .u form performs additional rounding up operations on the shifted results.

Description: The 8-bit data elements in Rs1 are right-shifted arithmetically, that is, the shifted out bits are filled with the sign-bit of the data elements. The shift amount is specified by the imm3u constant. For the rounding operation of the .u form, a value of 1 is added to the most significant discarded bit of each 8-bit data element to calculate the final results. And the results are written to Rd.

Operations:

```
sa = imm3u[2:0];
if (sa > 0) {
    if (`.u` form) { // SRA8.u
        res[7:-1] = SE9(Rs1.B[x][7:sa-1]) + 1;
        Rd.B[x] = res[7:0];
    } else { // SRA8
        Rd.B[x] = SE8(Rd.B[x][7:sa])
    }
} else {
    Rd = Rs1;
}
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

- [in] b: unsigned int type of value stored in b

__RV_SRAI8_U(a, b)

SRAI8.u (SIMD 8-bit Rounding Shift Right Arithmetic Immediate)

Type: SIMD

Syntax:

```
SRAI8 Rd, Rs1, imm3u
SRAI8.u Rd, Rs1, imm3u
```

Purpose: Do 8-bit element arithmetic right shift operations simultaneously. The shift amount is an immediate value. The .u form performs additional rounding up operations on the shifted results.

Description: The 8-bit data elements in Rs1 are right-shifted arithmetically, that is, the shifted out bits are filled with the sign-bit of the data elements. The shift amount is specified by the imm3u constant. For the rounding operation of the .u form, a value of 1 is added to the most significant discarded bit of each 8-bit data element to calculate the final results. And the results are written to Rd.

Operations:

__STATIC_FORCEINLINE unsigned long __RV_KSL8(unsigned long a, unsigned int b)
KSL8 (SIMD 8-bit Saturating Shift Left Logical)

Type: SIMD

Syntax:

KSL8 Rd, Rs1, Rs2

Purpose: Do 8-bit elements logical left shift operations with saturation simultaneously. The shift amount is a variable from a GPR.

Description: The 8-bit data elements in Rs1 are left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the low-order 3-bits of the value in the Rs2 register. Any shifted value greater than 2^7-1 is saturated to 2^7-1 . Any shifted value smaller than -2^7 is saturated to -2^7 . And the saturated results are written to Rd. If any saturation is performed, set OV bit to 1.

Operations:

<pre>sa = Rs2[2:0]; if (sa != 0) { res[(7+sa):0] = Rs1.B[x] << sa; if (res > (2^7)-1) { res = 0x7f; OV = 1; } else if (res < -2^7) { res = 0x80; OV = 1; } Rd.B[x] = res[7:0]; } else { Rd = Rs1; } for RV32: x=3...0, for RV64: x=7...0</pre>
--

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KSLRA8(unsigned long a, int b)
KSLRA8 (SIMD 8-bit Shift Left Logical with Saturation or Shift Right Arithmetic)

Type: SIMD

Syntax:

KSLRA8 Rd, Rs1, Rs2 KSLRA8.u Rd, Rs1, Rs2
--

Purpose: Do 8-bit elements logical left (positive) or arithmetic right (negative) shift operation with Q7 saturation for the left shift. The `.u` form performs additional rounding up operations for the right shift.

Description: The 8-bit data elements of `Rs1` are left-shifted logically or right-shifted arithmetically based on the value of `Rs2[3:0]`. `Rs2[3:0]` is in the signed range of $[-2^3, 2^3-1]$. A positive `Rs2[3:0]` means logical left shift and a negative `Rs2[3:0]` means arithmetic right shift. The shift amount is the absolute value of `Rs2[3:0]`. However, the behavior of `Rs2[3:0] == -2^3 (0x8)` is defined to be equivalent to the behavior of `Rs2[3:0] == -(2^3-1) (0x9)`. The left-shifted results are saturated to the 8-bit signed integer range of $[-2^7, 2^7-1]$. For the `.u` form of the instruction, the right-shifted results are added a 1 to the most significant discarded bit position for rounding effect. After the shift, saturation, or rounding, the final results are written to `Rd`. If any saturation happens, this instruction sets the OV flag. The value of `Rs2[31:4]` will not affect this instruction.

Operations:

```
if (Rs2[3:0] < 0) {
    sa = -Rs2[3:0];
    sa = (sa == 8)? 7 : sa;
    if (`u` form) {
        res[7:-1] = SE9(Rs1.B[x][7:sa-1]) + 1;
        Rd.B[x] = res[7:0];
    } else {
        Rd.B[x] = SE8(Rs1.B[x][7:sa]);
    }
} else {
    sa = Rs2[2:0];
    res[(7+sa):0] = Rs1.B[x] <<(logic) sa;
    if (res > (2^7)-1) {
        res[7:0] = 0x7f; OV = 1;
    } else if (res < -2^7) {
        res[7:0] = 0x80; OV = 1;
    }
    Rd.B[x] = res[7:0];
}
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] `a`: unsigned long type of value stored in `a`
- [in] `b`: int type of value stored in `b`

__STATIC_FORCEINLINE unsigned long __RV_KSLRA8_U(unsigned long a, int b)
KSLRA8.u (SIMD 8-bit Shift Left Logical with Saturation or Rounding Shift Right Arithmetic)

Type: SIMD

Syntax:

```
KSLRA8 Rd, Rs1, Rs2
KSLRA8.u Rd, Rs1, Rs2
```

Purpose: Do 8-bit elements logical left (positive) or arithmetic right (negative) shift operation with Q7 saturation for the left shift. The `.u` form performs additional rounding up operations for the right shift.

Description: The 8-bit data elements of `Rs1` are left-shifted logically or right-shifted arithmetically based on the value of `Rs2[3:0]`. `Rs2[3:0]` is in the signed range of $[-2^3, 2^3-1]$. A positive `Rs2[3:0]` means

logical left shift and a negative Rs2[3:0] means arithmetic right shift. The shift amount is the absolute value of Rs2[3:0]. However, the behavior of Rs2[3:0]==-2³ (0x8) is defined to be equivalent to the behavior of Rs2[3:0]==-(2³-1) (0x9). The left-shifted results are saturated to the 8-bit signed integer range of [-2⁷, 2⁷-1]. For the .u form of the instruction, the right-shifted results are added a 1 to the most significant discarded bit position for rounding effect. After the shift, saturation, or rounding, the final results are written to Rd. If any saturation happens, this instruction sets the OV flag. The value of Rs2[31:4] will not affect this instruction.

Operations:

```

if (Rs2[3:0] < 0) {
    sa = -Rs2[3:0];
    sa = (sa == 8)? 7 : sa;
    if (`.u` form) {
        res[7:-1] = SE9(Rs1.B[x][7:sa-1]) + 1;
        Rd.B[x] = res[7:0];
    } else {
        Rd.B[x] = SE8(Rs1.B[x][7:sa]);
    }
} else {
    sa = Rs2[2:0];
    res[(7+sa):0] = Rs1.B[x] <<(logic) sa;

group **NMSIS_Core_DSP_Intrinsic_SIMD_16B_CMP**

SIMD 16-bit Compare Instructions.

there are 5 SIMD 16-bit Compare instructions.

Functions

```
__STATIC_FORCEINLINE unsigned long __RV_CMPEQ16(unsigned long a, unsigned long b)
    CMPEQ16 (SIMD 16-bit Integer Compare Equal)
```

Type: SIMD

Syntax:

CMPEQ16 Rd, Rs1, Rs2

Purpose: Do 16-bit integer elements equal comparisons simultaneously.

Description: This instruction compares the 16-bit integer elements in Rs1 with the 16-bit integer elements in Rs2 to see if they are equal. If they are equal, the result is 0xFFFF; otherwise, the result is 0x0. The 16-bit element comparison results are written to Rt.

Note: This instruction can be used for either signed or unsigned numbers.

Operations:

Rd.H[x] = (Rs1.H[x] == Rs2.H[x])? 0xffff : 0x0; for RV32: x=1...0, for RV64: x=3...0
--

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_SCMPLT16(unsigned long a, unsigned long b)
    SCMPLE16 (SIMD 16-bit Signed Compare Less Than & Equal)
```

Type: SIMD

Syntax:

SCMPLE16 Rd, Rs1, Rs2

Purpose: Do 16-bit signed integer elements less than & equal comparisons simultaneously.

Description: This instruction compares the 16-bit signed integer elements in Rs1 with the 16-bit signed integer elements in Rs2 to see if the one in Rs1 is less than or equal to the one in Rs2. If it is true, the result is 0xFFFF; otherwise, the result is 0x0. The element comparison results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] {le} Rs2.H[x])? 0xffff : 0x0;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_SCMPLE16(unsigned long a, unsigned long b)
SCMPLE16 (SIMD 16-bit Signed Compare Less Than)

Type: SIMD

Syntax:

```
SCMPLE16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer elements less than comparisons simultaneously.

Description: This instruction compares the 16-bit signed integer elements in Rs1 with the two 16-bit signed integer elements in Rs2 to see if the one in Rs1 is less than the one in Rs2. If it is true, the result is 0xFFFF; otherwise, the result is 0x0. The element comparison results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] < Rs2.H[x])? 0xffff : 0x0;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UCMPLE16(unsigned long a, unsigned long b)
UCMPLE16 (SIMD 16-bit Unsigned Compare Less Than & Equal)

Type: SIMD

Syntax:

```
UCMPLE16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer elements less than & equal comparisons simultaneously.

Description: This instruction compares the 16-bit unsigned integer elements in Rs1 with the 16-bit unsigned integer elements in Rs2 to see if the one in Rs1 is less than or equal to the one in Rs2. If it is true, the result is 0xFFFF; otherwise, the result is 0x0. The element comparison results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] <=u Rs2.H[x])? 0xffff : 0x0;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UCMPLT16(unsigned long a, unsigned long b)
UCMPLT16 (SIMD 16-bit Unsigned Compare Less Than)

Type: SIMD

Syntax:

```
UCMPLT16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer elements less than comparisons simultaneously.

Description: This instruction compares the 16-bit unsigned integer elements in Rs1 with the 16-bit unsigned integer elements in Rs2 to see if the one in Rs1 is less than the one in Rs2. If it is true, the result is 0xFFFF; otherwise, the result is 0x0. The element comparison results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] <u Rs2.H[x])? 0xffff : 0x0;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

SIMD 8-bit Compare Instructions

```
__STATIC_FORCEINLINE unsigned long __RV_CMPEQ8(unsigned long a, unsigned long b)
__STATIC_FORCEINLINE unsigned long __RV_SCMPL8(unsigned long a, unsigned long b)
__STATIC_FORCEINLINE unsigned long __RV_SCMPLT8(unsigned long a, unsigned long b)

__STATIC_FORCEINLINE unsigned long __RV_UCMPLT8(unsigned long a, unsigned long b)
```

group **NMSIS_Core_DSP_Intrinsic_SIMD_8B_CMP**
SIMD 8-bit Compare Instructions.

there are 5 SIMD 8-bit Compare instructions.

Functions

__STATIC_FORCEINLINE unsigned long __RV_CMPEQ8(unsigned long a, unsigned long b)
 CMPEQ8 (SIMD 8-bit Integer Compare Equal)

Type: SIMD

Syntax:

```
CMPEQ8 Rs, Rs1, Rs2
```

Purpose: Do 8-bit integer elements equal comparisons simultaneously.

Description: This instruction compares the 8-bit integer elements in Rs1 with the 8-bit integer elements in Rs2 to see if they are equal. If they are equal, the result is 0xFF; otherwise, the result is 0x0. The 8-bit element comparison results are written to Rd.

Note: This instruction can be used for either signed or unsigned numbers.

Operations:

```
Rd.B[x] = (Rs1.B[x] == Rs2.B[x])? 0xff : 0x0;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_SCMPL8(unsigned long a, unsigned long b)
 SCMPLE8 (SIMD 8-bit Signed Compare Less Than & Equal)

Type: SIMD

Syntax:

```
SCMPLE8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer elements less than & equal comparisons simultaneously.

Description: This instruction compares the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2 to see if the one in Rs1 is less than or equal to the one in Rs2. If it is true, the result is 0xFF; otherwise, the result is 0x0. The element comparison results are written to Rd

Operations:

```
Rd.B[x] = (Rs1.B[x] {le} Rs2.B[x])? 0xff : 0x0;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_SCMLT8(unsigned long a, unsigned long b)
SCMLT8 (SIMD 8-bit Signed Compare Less Than)

Type: SIMD

Syntax:

```
SCMLT8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer elements less than comparisons simultaneously.

Description: This instruction compares the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2 to see if the one in Rs1 is less than the one in Rs2. If it is true, the result is 0xFF; otherwise, the result is 0x0. The element comparison results are written to Rd.

Operations:

```
Rd.B[x] = (Rs1.B[x] < Rs2.B[x])? 0xff : 0x0;  
for RV32: x=3...0,  
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UCMLE8(unsigned long a, unsigned long b)
UCMLE8 (SIMD 8-bit Unsigned Compare Less Than & Equal)

Type: SIMD

Syntax:

```
UCMLE8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer elements less than & equal comparisons simultaneously.

Description: This instruction compares the 8-bit unsigned integer elements in Rs1 with the 8-bit unsigned integer elements in Rs2 to see if the one in Rs1 is less than or equal to the one in Rs2. If it is true, the result is 0xFF; otherwise, the result is 0x0. The four comparison results are written to Rd.

Operations:

```
Rd.B[x] = (Rs1.B[x] <=u Rs2.B[x])? 0xff : 0x0;  
for RV32: x=3...0,  
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UCMLT8(unsigned long a, unsigned long b)
UCMLT8 (SIMD 8-bit Unsigned Compare Less Than)

Type: SIMD

Syntax:

```
UCMPLT8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer elements less than comparisons simultaneously.

Description: This instruction compares the 8-bit unsigned integer elements in Rs1 with the 8-bit unsigned integer elements in Rs2 to see if the one in Rs1 is less than the one in Rs2. If it is true, the result is 0xFF; otherwise, the result is 0x0. The element comparison results are written to Rd.

Operations:

```
Rd.B[x] = (Rs1.B[x] <u Rs2.B[x]) ? 0xff : 0x0;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

SIMD 16-bit Multiply Instructions

```
__STATIC_FORCEINLINE unsigned long __RV_KHM16(unsigned long a, unsigned long b)

__STATIC_FORCEINLINE unsigned long long __RV_UMUL16(unsigned int a, unsigned int b)
__STATIC_FORCEINLINE unsigned long long __RV_UMULX16(unsigned int a, unsigned int b)
```

group **NMSIS_Core_DSP_Intrinsic_SIMD_16B_MULTIPLY**

SIMD 16-bit Multiply Instructions.

there are 6 SIMD 16-bit Multiply instructions.

Functions

```
__STATIC_FORCEINLINE unsigned long __RV_KHM16(unsigned long a, unsigned long b)
KHM16 (SIMD Signed Saturating Q15 Multiply)
```

Type: SIMD

Syntax:

```
KHM16 Rd, Rs1, Rs2
KHMX16 Rd, Rs1, Rs2
```

Purpose: Do Q15xQ15 element multiplications simultaneously. The Q30 results are then reduced to Q15 numbers again.

Description: For the KHM16 instruction, multiply the top 16-bit Q15 content of 32-bit chunks in Rs1 with the top 16-bit Q15 content of 32-bit chunks in Rs2. At the same time, multiply the bottom 16-bit Q15 content of 32-bit chunks in Rs1 with the bottom 16-bit Q15 content of 32-bit chunks in Rs2. For the KHMX16 instruction, multiply the top 16-bit Q15 content of 32-bit chunks in Rs1 with the bottom 16-bit

Q15 content of 32-bit chunks in Rs2. At the same time, multiply the bottom 16-bit Q15 content of 32-bit chunks in Rs1 with the top 16-bit Q15 content of 32-bit chunks in Rs2. The Q30 results are then right-shifted 15-bits and saturated into Q15 values. The Q15 results are then written into Rd. When both the two Q15 inputs of a multiplication are 0x8000, saturation will happen. The result will be saturated to 0x7FFF and the overflow flag OV will be set.

Operations:

```
if (is `KHM16`) {
    op1t = Rs1.H[x+1]; op2t = Rs2.H[x+1]; // top
    op1b = Rs1.H[x]; op2b = Rs2.H[x]; // bottom
} else if (is `KHM16`) {
    op1t = Rs1.H[x+1]; op2t = Rs2.H[x]; // Rs1 top
    op1b = Rs1.H[x]; op2b = Rs2.H[x+1]; // Rs1 bottom
}
for ((aop,bop,res) in [(op1t,op2t,rest), (op1b,op2b,resb)]) {
    if (0x8000 != aop | 0x8000 != bop) {
        res = (aop s* bop) >> 15;
    } else {
        res= 0x7FFF;
        OV = 1;
    }
}
Rd.W[x/2] = concat(rest, resb);
for RV32: x=0
for RV64: x=0,2
```

Return value stored in unsigned long type

        OV = 1;
    }
}
Rd.W[x/2] = concat(rest, resb);
for RV32: x=0
for RV64: x=0,2

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_SMUL16(unsigned int a, unsigned int b)
 SMUL16 (SIMD Signed 16-bit Multiply)

Type: SIMD

Syntax:

```

SMUL16 Rd, Rs1, Rs2
SMULX16 Rd, Rs1, Rs2

```

Purpose: Do signed 16-bit multiplications and generate two 32-bit results simultaneously.

RV32 Description: For the SMUL16 instruction, multiply the top 16-bit Q15 content of Rs1 with the top 16-bit Q15 content of Rs2. At the same time, multiply the bottom 16-bit Q15 content of Rs1 with the bottom 16-bit Q15 content of Rs2. For the SMULX16 instruction, multiply the top 16-bit Q15 content of Rs1 with the bottom 16-bit Q15 content of Rs2. At the same time, multiply the bottom 16-bit Q15 content of Rs1 with the top 16-bit Q15 content of Rs2. The two Q30 results are then written into an even/odd pair of registers specified by Rd(4,1). Rd(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the 32-bit result calculated from the top part of Rs1 and the even 2d register of the pair contains the 32-bit result calculated from the bottom part of Rs1.

RV64 Description: For the SMUL16 instruction, multiply the top 16-bit Q15 content of the lower 32-bit word in Rs1 with the top 16-bit Q15 content of the lower 32-bit word in Rs2. At the same time, multiply the bottom 16-bit Q15 content of the lower 32-bit word in Rs1 with the bottom 16-bit Q15 content of the lower 32-bit word in Rs2. For the SMULX16 instruction, multiply the top 16-bit Q15 content of the lower 32-bit word in Rs1 with the bottom 16-bit Q15 content of the lower 32-bit word in Rs2. At the same time, multiply the bottom 16-bit Q15 content of the lower 32-bit word in Rs1 with the top 16-bit Q15 content of the lower 32-bit word in Rs2. The two 32-bit Q30 results are then written into Rd. The result calculated from the top 16-bit of the lower 32-bit word in Rs1 is written to Rd.W[1]. And the result calculated from the bottom 16-bit of the lower 32-bit word in Rs1 is written to Rd.W[0]

Operations:

```

* RV32:
if (is `SMUL16`) {
    op1t = Rs1.H[1]; op2t = Rs2.H[1]; // top
    op1b = Rs1.H[0]; op2b = Rs2.H[0]; // bottom
} else if (is `SMULX16`) {
    op1t = Rs1.H[1]; op2t = Rs2.H[0]; // Rs1 top
    op1b = Rs1.H[0]; op2b = Rs2.H[1]; // Rs1 bottom
}
for ((aop,bop,res) in [(op1t,op2t,rest), (op1b,op2b,resb)]) {
    res = aop s* bop;
}
t_L = CONCAT(Rd(4,1),1'b0); t_H = CONCAT(Rd(4,1),1'b1);
R[t_H] = rest;
R[t_L] = resb;
* RV64:
if (is `SMUL16`) {

SIMD 8-bit Multiply Instructions.

there are 6 SIMD 8-bit Multiply instructions.

Functions

```

__STATIC_FORCEINLINE unsigned long __RV_KHM8(unsigned long a, unsigned long b)
KHM8 (SIMD Signed Saturating Q7 Multiply)

```

Type: SIMD

Syntax:

```

KHM8 Rd, Rs1, Rs2
KHMX8 Rd, Rs1, Rs2

```

Purpose: Do Q7xQ7 element multiplications simultaneously. The Q14 results are then reduced to Q7 numbers again.

Description: For the KHM8 instruction, multiply the top 8-bit Q7 content of 16-bit chunks in Rs1 with the top 8-bit Q7 content of 16-bit chunks in Rs2. At the same time, multiply the bottom 8-bit Q7 content of 16-bit chunks in Rs1 with the bottom 8-bit Q7 content of 16-bit chunks in Rs2. For the KHMX16 instruction, multiply the top 8-bit Q7 content of 16-bit chunks in Rs1 with the bottom 8-bit Q7 content of 16-bit chunks in Rs2. At the same time, multiply the bottom 8-bit Q7 content of 16-bit chunks in Rs1 with the top 8-bit Q7 content of 16-bit chunks in Rs2. The Q14 results are then right-shifted 7-bits and saturated into Q7 values. The Q7 results are then written into Rd. When both the two Q7 inputs of a multiplication are 0x80, saturation will happen. The result will be saturated to 0x7F and the overflow flag OV will be set.

Operations:

```

if (is `KHM8`) {
    op1t = Rs1.B[x+1]; op2t = Rs2.B[x+1]; // top
    op1b = Rs1.B[x]; op2b = Rs2.B[x]; // bottom
} else if (is `KHMx8`) {
    op1t = Rs1.H[x+1]; op2t = Rs2.H[x]; // Rs1 top
    op1b = Rs1.H[x]; op2b = Rs2.H[x+1]; // Rs1 bottom
}
for ((aop,bop,res) in [(op1t,op2t,rest), (op1b,op2b,resb)]) {
    if (0x80 != aop | 0x80 != bop) {
        res = (aop s* bop) >> 7;
    } else {
        res= 0x7F;
        OV = 1;
    }
}

KHMx8 (SIMD Signed Saturating Crossed Q7 Multiply)

Type: SIMD

Syntax:

```

KHM8 Rd, Rs1, Rs2
KHMx8 Rd, Rs1, Rs2

```

Purpose: Do Q7xQ7 element multiplications simultaneously. The Q14 results are then reduced to Q7 numbers again.

Description: For the KHM8 instruction, multiply the top 8-bit Q7 content of 16-bit chunks in Rs1 with the top 8-bit Q7 content of 16-bit chunks in Rs2. At the same time, multiply the bottom 8-bit Q7 content of 16-bit chunks in Rs1 with the bottom 8-bit Q7 content of 16-bit chunks in Rs2. For the KHMx16 instruction, multiply the top 8-bit Q7 content of 16-bit chunks in Rs1 with the bottom 8-bit Q7 content of 16-bit chunks in Rs2. At the same time, multiply the bottom 8-bit Q7 content of 16-bit chunks in Rs1 with the top 8-bit Q7 content of 16-bit chunks in Rs2. The Q14 results are then right-shifted 7-bits and saturated into Q7 values. The Q7 results are then written into Rd. When both the two Q7 inputs of a multiplication are 0x80, saturation will happen. The result will be saturated to 0x7F and the overflow flag OV will be set.

Operations:

```

if (is `KHM8`) {

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_SMUL8(unsigned int a, unsigned int b)
SMUL8 (SIMD Signed 8-bit Multiply)

Type: SIMD

Syntax:

```

SMUL8 Rd, Rs1, Rs2
SMULX8 Rd, Rs1, Rs2

```

Purpose: Do signed 8-bit multiplications and generate four 16-bit results simultaneously.

RV32 Description: For the SMUL8 instruction, multiply the 8-bit data elements of Rs1 with the corresponding 8-bit data elements of Rs2. For the SMULX8 instruction, multiply the first and second 8-bit data elements of Rs1 with the second and first 8-bit data elements of Rs2. At the same time, multiply the third and fourth 8-bit data elements of Rs1 with the fourth and third 8-bit data elements of Rs2. The four 16-bit results are then written into an even/odd pair of registers specified by Rd(4,1). Rd(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the two 16-bit results calculated from the top part of Rs1 and the even 2d register of the pair contains the two 16-bit results calculated from the bottom part of Rs1.

RV64 Description: For the SMUL8 instruction, multiply the 8-bit data elements of Rs1 with the corresponding 8-bit data elements of Rs2. For the SMULX8 instruction, multiply the first and second 8-bit data elements of Rs1 with the second and first 8-bit data elements of Rs2. At the same time, multiply the third and fourth 8-bit data elements of Rs1 with the fourth and third 8-bit data elements of Rs2. The four 16-bit results are then written into Rd. The Rd.W[1] contains the two 16-bit results calculated from the top part of Rs1 and the Rd.W[0] contains the two 16-bit results calculated from the bottom part of Rs1.

Operations:

```

* RV32:
if (is `SMUL8`) {
    op1t[x/2] = Rs1.B[x+1]; op2t[x/2] = Rs2.B[x+1]; // top

Syntax:

```
SCLIP16 Rd, Rs1, imm4u[3:0]
```

Purpose: Limit the 16-bit signed integer elements of a register into a signed range simultaneously.

Description: This instruction limits the 16-bit signed integer elements stored in Rs1 into a signed integer range between $2^{\text{imm4u}}-1$ and -2^{imm4u} , and writes the limited results to Rd. For example, if imm4u is 3, the 16-bit input values should be saturated between 7 and -8. If saturation is performed, set OV bit to 1.

Operations:

```

src = Rs1.H[x];
if (src > (2^imm4u)-1) {
    src = (2^imm4u)-1;
    OV = 1;
} else if (src < -2^imm4u) {
    src = -2^imm4u;
    OV = 1;
}
Rd.H[x] = src
for RV32: x=1...0,
for RV64: x=3...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__RV_UCLIP16 (a, b)

UCLIP16 (SIMD 16-bit Unsigned Clip Value)

Type: SIMD**Syntax:**

UCLIP16 Rt, Ra, imm4u

Purpose: Limit the 16-bit signed elements of a register into an unsigned range simultaneously.**Description:** This instruction limits the 16-bit signed elements stored in Rs1 into an unsigned integer range between $2^{\text{imm4u}}-1$ and 0, and writes the limited results to Rd. For example, if imm4u is 3, the 16-bit input values should be saturated between 7 and 0. If saturation is performed, set OV bit to 1.**Operations:**

```

src = Rs1.H[x];
if (src > (2^imm4u)-1) {
    src = (2^imm4u)-1;
    OV = 1;
} else if (src < 0) {
    src = 0;
    OV = 1;
}
Rd.H[x] = src;
for RV32: x=1...0,
for RV64: x=3...0

```

Return value stored in unsigned long type**Parameters**

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

Functions

__STATIC_FORCEINLINE unsigned long __RV_CLRS16(unsigned long a)

CLRS16 (SIMD 16-bit Count Leading Redundant Sign)

Type: SIMD**Syntax:**

CLRS16 Rd, Rs1

Purpose: Count the number of redundant sign bits of the 16-bit elements of a general register.**Description:** Starting from the bits next to the sign bits of the 16-bit elements of Rs1, this instruction counts the number of redundant sign bits and writes the result to the corresponding 16-bit elements of Rd.**Operations:**

```

snum[x] = Rs1.H[x];
cnt[x] = 0;
for (i = 14 to 0) {
    if (snum[x](i) == snum[x](15)) {
        cnt[x] = cnt[x] + 1;
    }
}

```

(continues on next page)

(continued from previous page)

```

    } else {
        break;
    }
}
Rd.H[x] = cnt[x];
for RV32: x=1...0
for RV64: x=3...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_CLO16(unsigned long a)
CLO16 (SIMD 16-bit Count Leading One)

Type: SIMD

Syntax:

```
CLO16 Rd, Rs1
```

Purpose: Count the number of leading one bits of the 16-bit elements of a general register.

Description: Starting from the most significant bits of the 16-bit elements of Rs1, this instruction counts the number of leading one bits and writes the results to the corresponding 16-bit elements of Rd.

Operations:

```

snum[x] = Rs1.H[x];
cnt[x] = 0;
for (i = 15 to 0) {
    if (snum[x](i) == 1) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.H[x] = cnt[x];
for RV32: x=1...0
for RV64: x=3...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_CLZ16(unsigned long a)
CLZ16 (SIMD 16-bit Count Leading Zero)

Type: SIMD

Syntax:

```
CLZ16 Rd, Rs1
```

Purpose: Count the number of leading zero bits of the 16-bit elements of a general register.

Description: Starting from the most significant bits of the 16-bit elements of Rs1, this instruction counts the number of leading zero bits and writes the results to the corresponding 16-bit elements of Rd.

Operations:

```
snum[x] = Rs1.H[x];
cnt[x] = 0;
for (i = 15 to 0) {
    if (snum[x](i) == 0) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.H[x] = cnt[x];
for RV32: x=1...0
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_KABS16(unsigned long a)
KABS16 (SIMD 16-bit Saturating Absolute)

Type: SIMD

Syntax:

KABS16 Rd, Rs1

Purpose: Get the absolute value of 16-bit signed integer elements simultaneously.

Description: This instruction calculates the absolute value of 16-bit signed integer elements stored in Rs1 and writes the element results to Rd. If the input number is 0x8000, this instruction generates 0x7fff as the output and sets the OV bit to 1.

Operations:

```
src = Rs1.H[x];
if (src == 0x8000) {
    src = 0x7fff;
    OV = 1;
} else if (src[15] == 1)
    src = -src;
}
Rd.H[x] = src;
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_SMAX16(unsigned long a, unsigned long b)
SMAX16 (SIMD 16-bit Signed Maximum)

Type: SIMD

Syntax:

```
SMAX16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer elements finding maximum operations simultaneously.

Description: This instruction compares the 16-bit signed integer elements in Rs1 with the 16-bit signed integer elements in Rs2 and selects the numbers that is greater than the other one. The selected results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] > Rs2.H[x]) ? Rs1.H[x] : Rs2.H[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_SMIN16(unsigned long a, unsigned long b)
SMIN16 (SIMD 16-bit Signed Minimum)
```

Type: SIMD

Syntax:

```
SMIN16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit signed integer elements finding minimum operations simultaneously.

Description: This instruction compares the 16-bit signed integer elements in Rs1 with the 16-bit signed integer elements in Rs2 and selects the numbers that is less than the other one. The selected results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] < Rs2.H[x]) ? Rs1.H[x] : Rs2.H[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_UMAX16(unsigned long a, unsigned long b)
UMAX16 (SIMD 16-bit Unsigned Maximum)
```

Type: SIMD

Syntax:

```
UMAX16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer elements finding maximum operations simultaneously.

Description: This instruction compares the 16-bit unsigned integer elements in Rs1 with the 16-bit unsigned integer elements in Rs2 and selects the numbers that is greater than the other one. The selected results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] >u Rs2.H[x]) ? Rs1.H[x] : Rs2.H[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_UMIN16(unsigned long a, unsigned long b)
    UMIN16 (SIMD 16-bit Unsigned Minimum)
```

Type: SIMD

Syntax:

```
UMIN16 Rd, Rs1, Rs2
```

Purpose: Do 16-bit unsigned integer elements finding minimum operations simultaneously.

Description: This instruction compares the 16-bit unsigned integer elements in Rs1 with the 16-bit unsigned integer elements in Rs2 and selects the numbers that is less than the other one. The selected results are written to Rd.

Operations:

```
Rd.H[x] = (Rs1.H[x] <u Rs2.H[x]) ? Rs1.H[x] : Rs2.H[x];
for RV32: x=1...0,
for RV64: x=3...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

Defines

__RV_SCLIP8 (a, b)
SCLIP8 (SIMD 8-bit Signed Clip Value)

Type: SIMD

Syntax:

```
SCLIP8 Rd, Rs1, imm3u[2:0]
```

Purpose: Limit the 8-bit signed integer elements of a register into a signed range simultaneously.

Description: This instruction limits the 8-bit signed integer elements stored in Rs1 into a signed integer range between $2^{\text{imm3u}-1}$ and -2^{imm3u} , and writes the limited results to Rd. For example, if imm3u is 3, the 8-bit input values should be saturated between 7 and -8. If saturation is performed, set OV bit to 1.

Operations:

```

src = Rs1.B[x];
if (src > (2^imm3u)-1) {
    src = (2^imm3u)-1;
    OV = 1;
} else if (src < -2^imm3u) {
    src = -2^imm3u;
    OV = 1;
}
Rd.B[x] = src
for RV32: x=3...0,
for RV64: x=7...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

__RV_UCLIP8 (a, b)
UCLIP8 (SIMD 8-bit Unsigned Clip Value)

Type: SIMD

Syntax:

```
UCLIP8 Rt, Ra, imm3u
```

Purpose: Limit the 8-bit signed elements of a register into an unsigned range simultaneously.

Description: This instruction limits the 8-bit signed elements stored in Rs1 into an unsigned integer range between $2^{\text{imm3u}}-1$ and 0, and writes the limited results to Rd. For example, if imm3u is 3, the 8-bit input values should be saturated between 7 and 0. If saturation is performed, set OV bit to 1.

Operations:

```
src = Rs1.H[x];
if (src > (2^imm3u)-1) {
    src = (2^imm3u)-1;
    OV = 1;
} else if (src < 0) {
    src = 0;
    OV = 1;
}
Rd.H[x] = src;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

Functions

__STATIC_FORCEINLINE unsigned long __RV_CLRS8(unsigned long a)
CLRS8 (SIMD 8-bit Count Leading Redundant Sign)

Type: SIMD

Syntax:

```
CLRS8 Rd, Rs1
```

Purpose: Count the number of redundant sign bits of the 8-bit elements of a general register.

Description: Starting from the bits next to the sign bits of the 8-bit elements of Rs1, this instruction counts the number of redundant sign bits and writes the result to the corresponding 8-bit elements of Rd.

Operations:

```
snum[x] = Rs1.B[x];
cnt[x] = 0;
for (i = 6 to 0) {
    if (snum[x](i) == snum[x](7)) {
        cnt[x] = cnt[x] + 1;
    } else {

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_CLO8(unsigned long a)
CLO8 (SIMD 8-bit Count Leading One)

Type: SIMD

Syntax:

```
CLO8 Rd, Rs1
```

Purpose: Count the number of leading one bits of the 8-bit elements of a general register.

Description: Starting from the most significant bits of the 8-bit elements of Rs1, this instruction counts the number of leading one bits and writes the results to the corresponding 8-bit elements of Rd.

Operations:

```

snum[x] = Rs1.B[x];
cnt[x] = 0;
for (i = 7 to 0) {
    if (snum[x](i) == 1) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.B[x] = cnt[x];
for RV32: x=3...0
for RV64: x=7...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_CLZ8(unsigned long a)
CLZ8 (SIMD 8-bit Count Leading Zero)

Type: SIMD

Syntax:

```
CLZ8 Rd, Rs1
```

Purpose: Count the number of leading zero bits of the 8-bit elements of a general register.

Description: Starting from the most significant bits of the 8-bit elements of Rs1, this instruction counts the number of leading zero bits and writes the results to the corresponding 8-bit elements of Rd.

Operations:

```

snum[x] = Rs1.B[x];
cnt[x] = 0;
for (i = 7 to 0) {
    if (snum[x](i) == 0) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.B[x] = cnt[x];

for RV64: x=7...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_KABS8(unsigned long a)
KABS8 (SIMD 8-bit Saturating Absolute)

Type: SIMD

Syntax:

```
KABS8 Rd, Rs1
```

Purpose: Get the absolute value of 8-bit signed integer elements simultaneously.

Description: This instruction calculates the absolute value of 8-bit signed integer elements stored in Rs1 and writes the element results to Rd. If the input number is 0x80, this instruction generates 0x7f as the output and sets the OV bit to 1.

Operations:

```

src = Rs1.B[x];
if (src == 0x80) {
    src = 0x7f;
    OV = 1;
} else if (src[7] == 1)
    src = -src;
Rd.B[x] = src;
for RV32: x=3...0,
for RV64: x=7...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_SMAX8(unsigned long a, unsigned long b)
SMAX8 (SIMD 8-bit Signed Maximum)

Type: SIMD

Syntax:

```
SMAX8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer elements finding maximum operations simultaneously.

Description: This instruction compares the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2 and selects the numbers that is greater than the other one. The selected results are written to Rd.

Operations:

```
Rd.B[x] = (Rs1.B[x] > Rs2.B[x]) ? Rs1.B[x] : Rs2.B[x];
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_SMIN8(unsigned long a, unsigned long b)
SMIN8 (SIMD 8-bit Signed Minimum)

Type: SIMD

Syntax:

```
SMIN8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer elements finding minimum operations simultaneously.

Description: This instruction compares the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2 and selects the numbers that is less than the other one. The selected results are written to Rd.

Operations:

for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UMAX8(unsigned long a, unsigned long b)
UMAX8 (SIMD 8-bit Unsigned Maximum)

Type: SIMD

Syntax:

```
UMAX8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer elements finding maximum operations simultaneously.

Description: This instruction compares the 8-bit unsigned integer elements in Rs1 with the four 8-bit unsigned integer elements in Rs2 and selects the numbers that is greater than the other one. The two selected results are written to Rd.

Operations:

```
Rd.B[x] = (Rs1.B[x] >u Rs2.B[x]) ? Rs1.B[x] : Rs2.B[x];  
for RV32: x=3...0,  
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UMIN8(unsigned long a, unsigned long b)
UMIN8 (SIMD 8-bit Unsigned Minimum)

Type: SIMD

Syntax:

```
UMIN8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer elements finding minimum operations simultaneously.

Description: This instruction compares the 8-bit unsigned integer elements in Rs1 with the 8-bit unsigned integer elements in Rs2 and selects the numbers that is less than the other one. The selected results are written to Rd.

Operations:

```
Rd.B[x] = (Rs1.B[x] <u Rs2.B[x]) ? Rs1.B[x] : Rs2.B[x];  
for RV32: x=3...0,  
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

SIMD 8-bit Unpacking Instructions.

there are 8 SIMD 8-bit Unpacking instructions.

Functions

```
__STATIC_FORCEINLINE unsigned long __RV_SUNPKD810(unsigned long a)
SUNPKD810 (Signed Unpacking Bytes 1 & 0)
```

Type: DSP

Syntax:

```
SUNPKD8xy Rd, Rs1
xy = {10, 20, 30, 31, 32}
```

Purpose: Unpack byte *x* and byte *y* of 32-bit chunks in a register into two 16-bit signed halfwords of 32-bit chunks in a register.

Description: For the SUNPKD8 (*x*) (**y**) instruction, it unpacks byte *x* and byte *y* of 32-bit chunks in Rs1 into two 16-bit signed halfwords and writes the results to the top part and the bottom part of 32-bit chunks in Rd.

Operations:

```
Rd.W[m].H[1] = SE16(Rs1.W[m].B[x])
Rd.W[m].H[0] = SE16(Rs1.W[m].B[y])
// SUNPKD810, x=1,y=0
// SUNPKD820, x=2,y=0
// SUNPKD830, x=3,y=0

for RV32: m=0,
for RV64: m=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_SUNPKD832(unsigned long a)
 SUNPKD832 (Signed Unpacking Bytes 3 & 2)

Type: DSP

Syntax:

```
SUNPKD8xy Rd, Rs1
xy = {10, 20, 30, 31, 32}
```

Purpose: Unpack byte *x* and byte *y* of 32-bit chunks in a register into two 16-bit signed halfwords of 32-bit chunks in a register.

Description: For the SUNPKD8(*x*)(**y**) instruction, it unpacks byte *x* and byte *y* of 32-bit chunks in Rs1 into two 16-bit signed halfwords and writes the results to the top part and the bottom part of 32-bit chunks in Rd.

Operations:

```
Rd.W[m].H[1] = SE16(Rs1.W[m].B[x])
Rd.W[m].H[0] = SE16(Rs1.W[m].B[y])
// SUNPKD810, x=1,y=0
// SUNPKD820, x=2,y=0
// SUNPKD830, x=3,y=0
// SUNPKD831, x=3,y=1
// SUNPKD832, x=3,y=2
```

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_ZUNPKD810(unsigned long a)
 ZUNPKD810 (Unsigned Unpacking Bytes 1 & 0)

Type: DSP

Syntax:

```

ZUNPKD8xy Rd, Rs1
xy = {10, 20, 30, 31, 32}

```

Purpose: Unpack byte x and byte y of 32-bit chunks in a register into two 16-bit unsigned halfwords of 32-bit chunks in a register.

Description: For the ZUNPKD8 (x) (*y*) instruction, it unpacks byte *x and byte y* of 32-bit chunks in Rs1 into two 16-bit unsigned halfwords and writes the results to the top part and the bottom part of 32-bit chunks in Rd.

Operations:

```

Rd.W[m].H[1] = ZE16(Rs1.W[m].B[x])
Rd.W[m].H[0] = ZE16(Rs1.W[m].B[y])
// ZUNPKD810, x=1,y=0
// ZUNPKD820, x=2,y=0
// ZUNPKD830, x=3,y=0
// ZUNPKD831, x=3,y=1
// ZUNPKD832, x=3,y=2
for RV32: m=0,
for RV64: m=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_ZUNPKD820(unsigned long a)
 ZUNPKD820 (Unsigned Unpacking Bytes 2 & 0)

Type: DSP

Syntax:

```

ZUNPKD8xy Rd, Rs1
xy = {10, 20, 30, 31, 32}

```

Purpose: Unpack byte x and byte y of 32-bit chunks in a register into two 16-bit unsigned halfwords of 32-bit chunks in a register.

Description: For the ZUNPKD8 (x) (*y*) instruction, it unpacks byte *x and byte y* of 32-bit chunks in Rs1 into two 16-bit unsigned halfwords and writes the results to the top part and the bottom part of 32-bit chunks in Rd.

Operations:

```

Rd.W[m].H[1] = ZE16(Rs1.W[m].B[x])
Rd.W[m].H[0] = ZE16(Rs1.W[m].B[y])
// ZUNPKD810, x=1,y=0
// ZUNPKD820, x=2,y=0
// ZUNPKD830, x=3,y=0
// ZUNPKD831, x=3,y=1
// ZUNPKD832, x=3,y=2
for RV32: m=0,
for RV64: m=1...0

```

there are 7 Non-SIMD Q15 saturation ALU Instructions

Functions

```
__STATIC_FORCEINLINE long __RV_KADDH(int a, int b)
    KADDH (Signed Addition with Q15 Saturation)
```

Type: DSP

Syntax:

KADDH Rd, Rs1, Rs2

Purpose: Add the signed lower 32-bit content of two registers with Q15 saturation.

Description: The signed lower 32-bit content of Rs1 is added with the signed lower 32-bit content of Rs2. And the result is saturated to the 16-bit signed integer range of $[-2^{15}, 2^{15}-1]$ and then sign-extended and written to Rd. If saturation happens, this instruction sets the OV flag.

Operations:

<pre>tmp = Rs1.W[0] + Rs2.W[0]; if (tmp > 32767) { res = 32767; OV = 1; } else if (tmp < -32768) { res = -32768; OV = 1; } else { res = tmp; } Rd = SE(tmp[15:0]);</pre>
--

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE long __RV_KHMBB(unsigned int a, unsigned int b)

KHMBB (Signed Saturating Half Multiply B16 x B16)

Type: DSP

Syntax:

KHMxy Rd, Rs1, Rs2 (xy = BB, BT, TT)

Purpose: Multiply the signed Q15 number contents of two 16-bit data in the corresponding portion of the lower 32-bit chunk in registers and then right-shift 15 bits to turn the Q30 result into a Q15 number again and saturate the Q15 result into the destination register. If saturation happens, an overflow flag OV will be set.

Description: Multiply the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs1 with the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs2. The Q30 result is then right- shifted 15-bits and saturated into a Q15 value. The Q15 value is then sing-extended and written into Rd. When both the two Q15 inputs are 0x8000, saturation will happen. The result will be saturated to 0x7FFF and the overflow flag OV will be set.

Operations:

```
aop = Rs1.H[0]; bop = Rs2.H[0]; // KHMBB
aop = Rs1.H[0]; bop = Rs2.H[1]; // KHMBT
aop = Rs1.H[1]; bop = Rs2.H[1]; // KHMTT
If (0x8000 != aop | 0x8000 != bop) {
    Mresult[31:0] = aop * bop;
    res[15:0] = Mresult[30:15];
} else {
    res[15:0] = 0x7FFF;
    OV = 1;
}
Rd = SE32(res[15:0]); // Rv32
Rd = SE64(res[15:0]); // RV64
```

Return value stored in long type

Parameters

- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE long __RV_KSUBH(int a, int b)

KSUBH (Signed Subtraction with Q15 Saturation)

Type: DSP

Syntax:

```
KSUBH Rd, Rs1, Rs2
```

Purpose: Subtract the signed lower 32-bit content of two registers with Q15 saturation.

Description: The signed lower 32-bit content of Rs2 is subtracted from the signed lower 32-bit content of Rs1. And the result is saturated to the 16-bit signed integer range of $[-2^{15}, 2^{15}-1]$ and then sign-extended and written to Rd. If saturation happens, this instruction sets the OV flag.

Operations:

```

tmp = Rs1.W[0] - Rs2.W[0];
if (tmp > (2^15)-1) {
    res = (2^15)-1;
    OV = 1;
} else if (tmp < -2^15) {
    res = -2^15;
    OV = 1;
} else {

Defines

__RV_KSLLIW(a, b)
KSLLIW (Saturating Shift Left Logical Immediate for Word)

Type: DSP

Syntax:

```
KSLLIW Rd, Rs1, imm5u
```

Purpose: Do logical left shift operation with saturation on a 32-bit word. The shift amount is an immediate value.

Description: The first word data in Rs1 is left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the imm5u constant. Any shifted value greater than $2^{31}-1$ is saturated to $2^{31}-1$. Any shifted value smaller than -2^{31} is saturated to -2^{31} . And the saturated result is sign-extended and written to Rd. If any saturation is performed, set OV bit to 1.

Operations:

```

sa = imm5u;
res[(31+sa):0] = Rs1.W[0] << sa;
if (res > (2^31)-1) {
    res = 0x7fffffff; OV = 1;
} else if (res < -2^31) {
    res = 0x80000000; OV = 1;
}
Rd[31:0] = res[31:0]; // RV32
Rd[63:0] = SE(res[31:0]); // RV64

```

Return value stored in long type

Parameters

- [in] a: long type of value stored in a
- [in] b: unsigned int type of value stored in b

Functions

__STATIC_FORCEINLINE unsigned long __RV_KABSW(signed long a)
KABSW (Scalar 32-bit Absolute Value with Saturation)

Type: DSP

Syntax:

KABSW Rd, Rs1

Purpose: Get the absolute value of a signed 32-bit integer in a general register.

Description: This instruction calculates the absolute value of a signed 32-bit integer stored in Rs1. The result is sign-extended (for RV64) and written to Rd. This instruction with the minimum negative integer input of 0x80000000 will produce a saturated output of maximum positive integer of 0x7fffffff and the OV flag will be set to 1.

Operations:

```
if (Rs1.W[0] >= 0) {
    res = Rs1.W[0];
} else {
    If (Rs1.W[0] == 0x80000000) {
        res = 0x7fffffff;
        OV = 1;
    } else {
        res = -Rs1.W[0];
    }
}
Rd = SE32(res);
```

Return value stored in unsigned long type

Parameters

- [in] a: signed long type of value stored in a

__STATIC_FORCEINLINE long __RV_KADDW(int a, int b)
KADDW (Signed Addition with Q31 Saturation)

Type: DSP

Syntax:

KADDW Rd, Rs1, Rs2

Purpose: Add the lower 32-bit signed content of two registers with Q31 saturation.

Description: The lower 32-bit signed content of Rs1 is added with the lower 32-bit signed content of Rs2. And the result is saturated to the 32-bit signed integer range of $[-2^{31}, 2^{31}-1]$ and then sign-extended and written to Rd. If saturation happens, this instruction sets the OV flag.

Operations:

```

tmp = Rs1.W[0] + Rs2.W[0];
if (tmp > (2^31)-1) {
    res = (2^31)-1;
    OV = 1;
} else if (tmp < -2^31) {
    res = -2^31;
    OV = 1;
} else {
    res = tmp;
}
Rd = res[31:0]; // RV32
Rd = SE(res[31:0]) // RV64

```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE long __RV_KDMBB(unsigned int a, unsigned int b)
 KDMBB (Signed Saturating Double Multiply B16 x B16)

Type: DSP

Syntax:

```
KDMxy Rd, Rs1, Rs2 (xy = BB, BT, TT)
```

Purpose: Multiply the signed Q15 integer contents of two 16-bit data in the corresponding portion of the lower 32-bit chunk in registers and then double and saturate the Q31 result. The result is written into the destination register for RV32 or sign-extended to 64-bits and written into the destination register for RV64. If saturation happens, an overflow flag OV will be set.

Description: Multiply the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs1 with the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs2. The Q30 result is then doubled and saturated into a Q31 value. The Q31 value is then written into Rd (sign-extended in RV64). When both the two Q15 inputs are 0x8000, saturation will happen. The result will be saturated to 0x7FFFFFFF and the overflow flag OV will be set.

Operations:

```

aop = Rs1.H[0]; bop = Rs2.H[0]; // KDMBB
aop = Rs1.H[0]; bop = Rs2.H[1]; // KDMBT
aop = Rs1.H[1]; bop = Rs2.H[1]; // KDMTT
If (0x8000 != aop | 0x8000 != bop) {
    Mresult = aop * bop;
    resQ31 = Mresult << 1;
    Rd = resQ31; // RV32
    Rd = SE(resQ31); // RV64
} else {
    resQ31 = 0x7FFFFFFF;
    Rd = resQ31; // RV32
    Rd = SE(resQ31); // RV64
    OV = 1;
}

```

Return value stored in long type

Parameters

- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE long __RV_KDMBT(unsigned int a, unsigned int b)

KDMBT (Signed Saturating Double Multiply B16 x T16)

Type: DSP

Syntax:

KDMxy Rd, Rs1, Rs2 (xy = BB, BT, TT)

Purpose: Multiply the signed Q15 integer contents of two 16-bit data in the corresponding portion of the lower 32-bit chunk in registers and then double and saturate the Q31 result. The result is written into the destination register for RV32 or sign-extended to 64-bits and written into the destination register for RV64. If saturation happens, an overflow flag OV will be set.

Description: Multiply the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs1 with the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs2. The Q30 result is then doubled and saturated into a Q31 value. The Q31 value is then written into Rd (sign-extended in RV64). When both the two Q15 inputs are 0x8000, saturation will happen. The result will be saturated to 0x7FFFFFFF and the overflow flag OV will be set.

Operations:

```
aop = Rs1.H[0]; bop = Rs2.H[0]; // KDMBB
aop = Rs1.H[0]; bop = Rs2.H[1]; // KDMBT
aop = Rs1.H[1]; bop = Rs2.H[1]; // KDMTT
If (0x8000 != aop | 0x8000 != bop) {
    Mresult = aop * bop;
    resQ31 = Mresult << 1;
    Rd = resQ31; // RV32
    Rd = SE(resQ31); // RV64
} else {
    resQ31 = 0x7FFFFFFF;
    Rd = resQ31; // RV32
    Rd = SE(resQ31); // RV64
    OV = 1;
}
```

Return value stored in long type

Parameters

- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE long __RV_KDMTT(unsigned int a, unsigned int b)

KDMTT (Signed Saturating Double Multiply T16 x T16)

Type: DSP

Syntax:

KDMxy Rd, Rs1, Rs2 (xy = BB, BT, TT)

Purpose: Multiply the signed Q15 integer contents of two 16-bit data in the corresponding portion of the lower 32-bit chunk in registers and then double and saturate the Q31 result. The result is written into the

destination register for RV32 or sign-extended to 64-bits and written into the destination register for RV64. If saturation happens, an overflow flag OV will be set.

Description: Multiply the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs1 with the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs2. The Q30 result is then doubled and saturated into a Q31 value. The Q31 value is then written into Rd (sign-extended in RV64). When both the two Q15 inputs are 0x8000, saturation will happen. The result will be saturated to 0x7FFFFFFF and the overflow flag OV will be set.

Operations:

```
aop = Rs1.H[0]; bop = Rs2.H[0]; // KDMBB
aop = Rs1.H[0]; bop = Rs2.H[1]; // KDMBT
aop = Rs1.H[1]; bop = Rs2.H[1]; // KDMTT
If (0x8000 != aop | 0x8000 != bop) {
    Mresult = aop * bop;
    resQ31 = Mresult << 1;
    Rd = resQ31; // RV32
    Rd = SE(resQ31); // RV64
} else {
    resQ31 = 0x7FFFFFFF;
    Rd = resQ31; // RV32
    Rd = SE(resQ31); // RV64
    OV = 1;
}
```

Return value stored in long type

Parameters

- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE long __RV_KDMABB(long t, unsigned int a, unsigned int b)
KDMABB (Signed Saturating Double Multiply Addition B16 x B16)

Type: DSP

Syntax:

```
KDMAxy Rd, Rs1, Rs2 (xy = BB, BT, TT)
```

Purpose: Multiply the signed Q15 integer contents of two 16-bit data in the corresponding portion of the lower 32-bit chunk in registers and then double and saturate the Q31 result, add the result with the sign-extended lower 32-bit chunk destination register and write the saturated addition result into the destination register. If saturation happens, an overflow flag OV will be set.

Description: Multiply the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs1 with the top or bottom 16-bit Q15 content of the lower 32-bit portion in Rs2. The Q30 result is then doubled and saturated into a Q31 value. The Q31 value is then added with the content of Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV flag is set to 1. The result after saturation is written to Rd. When both the two Q15 inputs are 0x8000, saturation will happen and the overflow flag OV will be set.

Operations:

```
aop = Rs1.H[0]; bop = Rs2.H[0]; // KDMABB
aop = Rs1.H[0]; bop = Rs2.H[1]; // KDMABT
aop = Rs1.H[1]; bop = Rs2.H[1]; // KDMATT
```

```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE long __RV_KSLW(long a, unsigned int b)
KSLW (Saturating Shift Left Logical for Word)

Type: DSP

Syntax:

```
KSLW Rd, Rs1, Rs2
```

Purpose: Do logical left shift operation with saturation on a 32-bit word. The shift amount is a variable from a GPR.

Description: The first word data in Rs1 is left-shifted logically. The shifted out bits are filled with zero and the shift amount is specified by the low-order 5-bits of the value in the Rs2 register. Any shifted value greater than $2^{31}-1$ is saturated to $2^{31}-1$. Any shifted value smaller than -2^{31} is saturated to -2^{31} . And the saturated result is sign-extended and written to Rd. If any saturation is performed, set OV bit to 1.

Operations:

```

sa = Rs2[4:0];
res[(31+sa):0] = Rs1.W[0] << sa;
if (res > (2^31)-1) {
    res = 0x7fffffff; OV = 1;
} else if (res < -2^31) {
    res = 0x80000000; OV = 1;
}
Rd[31:0] = res[31:0]; // RV32
Rd[63:0] = SE(res[31:0]); // RV64

```

Return value stored in long type

Parameters

- [in] a: long type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE long __RV_KSLRAW(int a, int b)
 KSLRAW (Shift Left Logical with Q31 Saturation or Shift Right Arithmetic)

Type: DSP

Syntax:

KSLRAW Rd, Rs1, Rs2

Purpose: Perform a logical left (positive) or arithmetic right (negative) shift operation with Q31 saturation for the left shift on a 32-bit data.

Description: The lower 32-bit content of Rs1 is left-shifted logically or right-shifted arithmetically based on the value of Rs2[5:0]. Rs2[5:0] is in the signed range of [-25, 25-1]. A positive Rs2[5:0] means logical left shift and a negative Rs2[5:0] means arithmetic right shift. The shift amount is the absolute value of Rs2[5:0] clamped to the actual shift range of [0, 31]. The left-shifted result is saturated to the 32-bit signed integer range of $[-2^{31}, 2^{31}-1]$. After the shift operation, the final result is bit-31 sign-extended and written to Rd. If any saturation happens, this instruction sets the OV flag. The value of Rs2[31:6] will not affected the operation of this instruction.

Operations:

```
if (Rs2[5:0] < 0) {
    sa = -Rs2[5:0];
    sa = (sa == 32)? 31 : sa;
    res[31:0] = Rs1.W[0] >>(arith) sa;
} else {
    sa = Rs2[5:0];
    tmp = Rs1.W[0] <<(logic) sa;
    if (tmp > (2^31)-1) {
        res[31:0] = (2^31)-1;
        OV = 1;
    } else if (tmp < -2^31) {
        res[31:0] = -2^31;
        OV = 1;
    } else {
        res[31:0] = tmp[31:0];
    }
}
Rd = res[31:0]; // RV32
Rd = SE64(res[31:0]); // RV64
```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE long __RV_KSLRAW_U(int a, int b)
 KSLRAW.u (Shift Left Logical with Q31 Saturation or Rounding Shift Right Arithmetic)

Type: DSP

Syntax:

KSLRAW.u Rd, Rs1, Rs2

Purpose: Perform a logical left (positive) or arithmetic right (negative) shift operation with Q31 saturation for the left shift and a rounding up operation for the right shift on a 32-bit data.

Description: The lower 32-bit content of Rs1 is left-shifted logically or right-shifted arithmetically based on the value of Rs2[5:0]. Rs2[5:0] is in the signed range of [-25, 25-1]. A positive Rs2[5:0] means logical left shift and a negative Rs2[5:0] means arithmetic right shift. The shift amount is the absolute value of Rs2[5:0] clamped to the actual shift range of [0, 31]. The left-shifted result is saturated to the 32-bit signed integer range of $[-2^{31}, 2^{31}-1]$. The right-shifted result is added a 1 to the most significant discarded bit position for rounding effect. After the shift, saturation, or rounding, the final result is bit-31 sign-extended and written to Rd. If any saturation happens, this instruction sets the OV flag. The value of Rs2[31:6] will not affect the operation of this instruction.

Operations:

```

if (Rs2[5:0] < 0) {
    sa = -Rs2[5:0];
    sa = (sa == 32)? 31 : sa;
    res[31:-1] = SE33(Rs1[31:(sa-1)]) + 1;
    rst[31:0] = res[31:0];
} else {
    sa = Rs2[5:0];
    tmp = Rs1.W[0] <<(logic) sa;
    if (tmp > (2^31)-1) {
        rst[31:0] = (2^31)-1;
        OV = 1;
    } else if (tmp < -2^31) {
        rst[31:0] = -2^31;
        OV = 1;
    } else {
        rst[31:0] = tmp[31:0];
    }
}
Rd = rst[31:0]; // RV32
Rd = SE64(rst[31:0]); // RV64

```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE long __RV_KSUBW(int a, int b)
 KSUBW (Signed Subtraction with Q31 Saturation)

Type: DSP

Syntax:

```
KSUBW Rd, Rs1, Rs2
```

Purpose: Subtract the signed lower 32-bit content of two registers with Q31 saturation.

Description: The signed lower 32-bit content of Rs2 is subtracted from the signed lower 32-bit content of Rs1. And the result is saturated to the 32-bit signed integer range of $[-2^{31}, 2^{31}-1]$ and then sign-extended and written to Rd. If saturation happens, this instruction sets the OV flag.

Operations:

```

tmp = Rs1.W[0] - Rs2.W[0];
if (tmp > (2^31)-1) {
    res = (2^31)-1;

```

(continues on next page)

(continued from previous page)

```

    OV = 1;
} else if (tmp < -2^31) {
res = -2^31;
    OV = 1;
} else {
    res = tmp;
}
Rd = res[31:0]; // RV32
Rd = SE(res[31:0]); // RV64

```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKADDW(unsigned int a, unsigned int b)
UKADDW (Unsigned Addition with U32 Saturation)

Type: DSP

Syntax:

```
UKADDW Rd, Rs1, Rs2
```

Purpose: Add the unsigned lower 32-bit content of two registers with U32 saturation.

Description: The unsigned lower 32-bit content of Rs1 is added with the unsigned lower 32-bit content of Rs2. And the result is saturated to the 32-bit unsigned integer range of [0, 2³²-1] and then sign-extended and written to Rd. If saturation happens, this instruction sets the OV flag.

Operations:

```

tmp = Rs1.W[0] + Rs2.W[0];
if (tmp > (2^32)-1) {
    tmp[31:0] = (2^32)-1;
    OV = 1;
}
Rd = tmp[31:0]; // RV32
Rd = SE(tmp[31:0]); // RV64

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKSUBW(unsigned int a, unsigned int b)
UKSUBW (Unsigned Subtraction with U32 Saturation)

Type: DSP

Syntax:

```
UKSUBW Rd, Rs1, Rs2
```

Purpose: Subtract the unsigned lower 32-bit content of two registers with unsigned 32-bit saturation.

Description: The unsigned lower 32-bit content of Rs2 is subtracted from the unsigned lower 32-bit content of Rs1. And the result is saturated to the 32-bit unsigned integer range of [0, 2³²-1] and then sign-extended and written to Rd. If saturation happens, this instruction sets the OV flag.

Operations:

```
tmp = Rs1.W[0] - Rs2.W[0];
if (tmp < 0) {
    tmp[31:0] = 0;
    OV = 1;
}
Rd = tmp[31:0]; // RV32
Rd = SE(tmp[31:0]); // RV64
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

32-bit Computation Instructions

```

group NMSIS_Core_DSP_Intrinsic_32B_COMPUTATION

32-bit Computation Instructions

there are 8 32-bit Computation Instructions

Functions

```
__STATIC_FORCEINLINE long __RV_MAXW(int a, int b)
MAXW (32-bit Signed Word Maximum)
```

Type: DSP

Syntax:

```
MAXW Rd, Rs1, Rs2
```

Purpose: Get the larger value from the 32-bit contents of two general registers.

Description: This instruction compares two signed 32-bit integers stored in Rs1 and Rs2, picks the larger value as the result, and writes the result to Rd.

Operations:

```
if (Rs1.W[0] >= Rs2.W[0]) {
    Rd = SE(Rs1.W[0]);
} else {
    Rd = SE(Rs2.W[0]);
}
```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE long __RV_MINW(int a, int b)
MINW (32-bit Signed Word Minimum)

Type: DSP

Syntax:

```
MINW Rd, Rs1, Rs2
```

Purpose: Get the smaller value from the 32-bit contents of two general registers.

Description: This instruction compares two signed 32-bit integers stored in Rs1 and Rs2, picks the smaller value as the result, and writes the result to Rd.

Operations:

```
if (Rs1.W[0] >= Rs2.W[0]) { Rd = SE(Rs2.W[0]); } else { Rd = SE(Rs1.W[0]); }
```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_MULR64(unsigned long a, unsigned long b)
MULR64 (Multiply Word Unsigned to 64-bit Data)

Type: DSP

Syntax:

```
MULR64 Rd, Rs1, Rs2
```

Purpose: Multiply the 32-bit unsigned integer contents of two registers and write the 64-bit result.

RV32 Description: This instruction multiplies the 32-bit content of Rs1 with that of Rs2 and writes the 64-bit multiplication result to an even/odd pair of registers containing Rd. Rd(4,1) index d determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair

contains the low 32-bit of the result. The lower 32-bit contents of Rs1 and Rs2 are treated as unsigned integers.

RV64 Description: This instruction multiplies the lower 32-bit content of Rs1 with that of Rs2 and writes the 64-bit multiplication result to Rd. The lower 32-bit contents of Rs1 and Rs2 are treated as unsigned integers.

Operations:

```
RV32:
Mresult = CONCAT(1`b0, Rs1) u* CONCAT(1`b0, Rs2);
R[Rd(4,1).1(0)][31:0] = Mresult[63:32];
R[Rd(4,1).0(0)][31:0] = Mresult[31:0];
RV64:
Rd = Mresult[63:0];
Mresult = CONCAT(1`b0, Rs1.W[0]) u* CONCAT(1`b0, Rs2.W[0]);
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_MULSR64(long a, long b)

MULSR64 (Multiply Word Signed to 64-bit Data)

Type: DSP

Syntax:

```
MULSR64 Rd, Rs1, Rs2
```

Purpose: Multiply the 32-bit signed integer contents of two registers and write the 64-bit result.

RV32 Description: This instruction multiplies the lower 32-bit content of Rs1 with the lower 32-bit content of Rs2 and writes the 64-bit multiplication result to an even/odd pair of registers containing Rd. Rd(4,1) index d determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result. The lower 32-bit contents of Rs1 and Rs2 are treated as signed integers.

RV64 Description: This instruction multiplies the lower 32-bit content of Rs1 with the lower 32-bit content of Rs2 and writes the 64-bit multiplication result to Rd. The lower 32-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```
RV32:
Mresult = Ra s* Rb;
R[Rd(4,1).1(0)][31:0] = Mresult[63:32];
R[Rd(4,1).0(0)][31:0] = Mresult[31:0];
RV64:
Mresult = Ra.W[0] s* Rb.W[0];
Rd = Mresult[63:0];
```

Return value stored in long long type

Parameters

- [in] a: long type of value stored in a
- [in] b: long type of value stored in b

__STATIC_FORCEINLINE long __RV_RADDW(int a, int b)

RADDW (32-bit Signed Halving Addition)

Type: DSP

Syntax:

```
RADDW Rd, Rs1, Rs2
```

Purpose: Add 32-bit signed integers and the results are halved to avoid overflow or saturation.

Description: This instruction adds the first 32-bit signed integer in Rs1 with the first 32-bit signed integer in Rs2. The result is first arithmetically right-shifted by 1 bit and then sign-extended and written to Rd.

Examples:

```
* Rs1 = 0x7FFFFFFF, Rs2 = 0x7FFFFFFF, Rd = 0x7FFFFFFF
* Rs1 = 0x80000000, Rs2 = 0x80000000, Rd = 0x80000000
* Rs1 = 0x40000000, Rs2 = 0x80000000, Rd = 0xE0000000
```

Operations:

```
RV32:
Rd[31:0] = (Rs1[31:0] + Rs2[31:0]) s>> 1;
RV64:
resw[31:0] = (Rs1[31:0] + Rs2[31:0]) s>> 1;
Rd[63:0] = SE(resw[31:0]);
```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE long __RV_RSUBW(int a, int b)

RSUBW (32-bit Signed Halving Subtraction)

Type: DSP

Syntax:

```
RSUBW Rd, Rs1, Rs2
```

Purpose: Subtract 32-bit signed integers and the result is halved to avoid overflow or saturation.

Description: This instruction subtracts the first 32-bit signed integer in Rs2 from the first 32-bit signed integer in Rs1. The result is first arithmetically right-shifted by 1 bit and then sign-extended and written to Rd.

Examples:

```
* Rs1 = 0x7FFFFFFF, Rs2 = 0x80000000, Rd = 0x7FFFFFFF
* Rs1 = 0x80000000, Rs2 = 0x7FFFFFFF, Rd = 0x80000000
* Rs1 = 0x80000000, Rs2 = 0x40000000, Rd = 0xA0000000
```

Operations:

```
RV32:
Rd[31:0] = (Rs1[31:0] - Rs2[31:0]) s>> 1;
RV64:
resw[31:0] = (Rs1[31:0] - Rs2[31:0]) s>> 1;
Rd[63:0] = SE(resw[31:0]);
```

Return value stored in long type

Parameters

- [in] a: int type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URADDW(unsigned int a, unsigned int b)
URADDW (32-bit Unsigned Halving Addition)

Type: DSP

Syntax:

```
URADDW Rd, Rs1, Rs2
```

Purpose: Add 32-bit unsigned integers and the results are halved to avoid overflow or saturation.

Description: This instruction adds the first 32-bit unsigned integer in Rs1 with the first 32-bit unsigned integer in Rs2. The result is first logically right-shifted by 1 bit and then sign-extended and written to Rd.

Examples:

```
* Ra = 0x7FFFFFFF, Rb = 0x7FFFFFFF Rt = 0x7FFFFFFF
* Ra = 0x80000000, Rb = 0x80000000 Rt = 0x80000000
* Ra = 0x40000000, Rb = 0x80000000 Rt = 0x60000000
```

Operations:

```
* RV32:
Rd[31:0] = (Rs1[31:0] + Rs2[31:0]) u>> 1;
* RV64:
resw[31:0] = (Rs1[31:0] + Rs2[31:0]) u>> 1;
Rd[63:0] = SE(resw[31:0]);
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URSUBW(unsigned int a, unsigned int b)
URSUBW (32-bit Unsigned Halving Subtraction)

Type: DSP

Syntax:

```
URSUBW Rd, Rs1, Rs2
```

Purpose: Subtract 32-bit unsigned integers and the result is halved to avoid overflow or saturation.

Description: This instruction subtracts the first 32-bit signed integer in Rs2 from the first 32-bit signed integer in Rs1. The result is first logically right-shifted by 1 bit and then sign-extended and written to Rd.

Examples:

```
* Ra = 0x7FFFFFFF, Rb = 0x80000000 Rt = 0xFFFFFFFF
* Ra = 0x80000000, Rb = 0x7FFFFFFF Rt = 0x00000000
* Ra = 0x80000000, Rb = 0x40000000 Rt = 0x20000000
```

Operations:

```
* RV32:
Rd[31:0] = (Rs1[31:0] - Rs2[31:0]) u>> 1;
* RV64:
resw[31:0] = (Rs1[31:0] - Rs2[31:0]) u>> 1;
Rd[63:0] = SE(resw[31:0]);
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned int type of value stored in a
- [in] b: unsigned int type of value stored in b

OV (Overflow) flag Set/Clear Instructions

OV (Overflow) flag Set/Clear Instructions.

The following table lists the user instructions related to Overflow (OV) flag manipulation. there are 2 OV (Overflow) flag Set/Clear Instructions

Functions

```
__STATIC_FORCEINLINE void __RV_CLROV(void)
```

CLROV (Clear OV flag)

Type: DSP

Syntax:

```
CLROV # pseudo mnemonic
```

Purpose: This pseudo instruction is an alias to CSRRCI x0, ucode, 1 instruction.

```
__STATIC_FORCEINLINE unsigned long __RV_RDOV(void)
```

RDOV (Read OV flag)

Type: DSP

Syntax:

```
RDOV Rd # pseudo mnemonic
```

Purpose: This pseudo instruction is an alias to CSRR Rd, ucode instruction which maps to the real instruction of CSRRS Rd, ucode, x0.

Return value stored in unsigned long type

Functions

```
__STATIC_FORCEINLINE unsigned long __RV_PKBB16(unsigned long a, unsigned long b)
PKBB16 (Pack Two 16-bit Data from Both Bottom Half)
```

Type: DSP

Syntax:

```
PKBB16 Rd, Rs1, Rs2
PKBT16 Rd, Rs1, Rs2
PKTT16 Rd, Rs1, Rs2
PKTB16 Rd, Rs1, Rs2
```

Purpose: Pack 16-bit data from 32-bit chunks in two registers.

- PKBB16: bottom.bottom
- PKBT16 bottom.top
- PKTT16 top.top
- PKTB16 top.bottom

Description: (PKBB16) moves Rs1.W[x][15:0] to Rd.W[x][31:16] and moves Rs2.W[x] [15:0] to Rd.W[x] [15:0]. (PKBT16) moves Rs1.W[x] [15:0] to Rd.W[x] [31:16] and moves Rs2.W[x] [31:16] to Rd.W[x] [15:0]. (PKTT16) moves Rs1.W[x] [31:16] to Rd.W[x] [31:16] and moves Rs2.W[x] [31:16] to Rd.W[x] [15:0]. (PKTB16) moves Rs1.W[x] [31:16] to Rd.W[x] [31:16] and moves Rs2.W[x] [15:0] to Rd.W[x] [15:0].

Operations:

```

Rd.W[x][31:0] = CONCAT(Rs1.W[x][15:0], Rs2.W[x][15:0]); // PKBB16
Rd.W[x][31:0] = CONCAT(Rs1.W[x][15:0], Rs2.W[x][31:16]); // PKBT16
Rd.W[x][31:0] = CONCAT(Rs1.W[x][31:16], Rs2.W[x][15:0]); // PKTB16

group **NMSIS_Core_DSP_Intrinsic_SIGNED_MSW_32X32_MAC**

Signed MSW 32x32 Multiply and Add Instructions.

there are 8 Signed MSW 32x32 Multiply and Add Instructions

Functions

```
__STATIC_FORCEINLINE long __RV_KMMAC(long t, long a, long b)
KMMAC (SIMD Saturating MSW Signed Multiply Word and Add)
```

Type: SIMD

Syntax:

```
KMMAC Rd, Rs1, Rs2
KMMAC.u Rd, Rs1, Rs2
```

Purpose: Multiply the signed 32-bit integer elements of two registers and add the most significant 32-bit results with the signed 32-bit integer elements of a third register. The addition results are saturated first and then written back to the third register. The `.u` form performs an additional rounding up operation on the multiplication results before adding the most significant 32-bit part of the results.

Description: This instruction multiplies the signed 32-bit elements of Rs1 with the signed 32-bit elements of Rs2 and adds the most significant 32-bit multiplication results with the signed 32-bit elements of Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to 1. The results after saturation are written to Rd. The `.u` form of the instruction additionally rounds up the most significant 32-bit of the 64-bit multiplication results by adding a 1 to bit 31 of the results.

Operations:

```
Mres[x][63:0] = Rs1.W[x] * Rs2.W[x];
if (`.u` form) {
    Round[x][32:0] = Mres[x][63:31] + 1;
    res[x] = Rd.W[x] + Round[x][32:1];
} else {
    res[x] = Rd.W[x] + Mres[x][63:32];
}
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: long type of value stored in a
- [in] b: long type of value stored in b

__STATIC_FORCEINLINE long __RV_KWMUL(long a, long b)
 KWMUL (SIMD Saturating MSW Signed Multiply Word & Double)

Type: SIMD

Syntax:

```

KWMUL Rd, Rs1, Rs2
KWMUL.u Rd, Rs1, Rs2

```

Purpose: Multiply the signed 32-bit integer elements of two registers, shift the results left 1-bit, saturate, and write the most significant 32-bit results to a register. The `.u` form additionally rounds up the multiplication results from the most significant discarded bit.

Description: This instruction multiplies the 32-bit elements of Rs1 with the 32-bit elements of Rs2. It then shifts the multiplication results one bit to the left and takes the most significant 32-bit results. If the shifted result is greater than $2^{31}-1$, it is saturated to $2^{31}-1$ and the OV flag is set to 1. The final element result is written to Rd. The 32-bit elements of Rs1 and Rs2 are treated as signed integers. The `.u` form of the instruction additionally rounds up the 64-bit multiplication results by adding a 1 to bit 30 before the shift and saturation operations.

Operations:

```

if ((0x80000000 != Rs1.W[x]) | (0x80000000 != Rs2.W[x])) {
    Mres[x][63:0] = Rs1.W[x] * Rs2.W[x];
    if (`.u` form) {

```

Return value stored in long type

Parameters

- [in] a: long type of value stored in a
- [in] b: long type of value stored in b

__STATIC_FORCEINLINE long __RV_KWMUL U(long a, long b)

KWMMUL.u (SIMD Saturating MSW Signed Multiply Word & Double with Rounding)

Type: SIMD**Syntax:**

KWMMUL Rd, Rs1, Rs2
 KWMMUL.u Rd, Rs1, Rs2

Purpose: Multiply the signed 32-bit integer elements of two registers, shift the results left 1-bit, saturate, and write the most significant 32-bit results to a register. The .u form additionally rounds up the multiplication results from the most significant discarded bit.

Description: This instruction multiplies the 32-bit elements of Rs1 with the 32-bit elements of Rs2. It then shifts the multiplication results one bit to the left and takes the most significant 32-bit results. If the shifted result is greater than $2^{31}-1$, it is saturated to $2^{31}-1$ and the OV flag is set to 1. The final element result is written to Rd. The 32-bit elements of Rs1 and Rs2 are treated as signed integers. The .u form of the instruction additionally rounds up the 64-bit multiplication results by adding a 1 to bit 30 before the shift and saturation operations.

Operations:

```

if ((0x80000000 != Rs1.W[x]) | (0x80000000 != Rs2.W[x])) {
    Mres[x][63:0] = Rs1.W[x] * Rs2.W[x];
    if (`.u` form) {
        Round[x][33:0] = Mres[x][63:30] + 1;
        Rd.W[x] = Round[x][32:1];
    } else {
        Rd.W[x] = Mres[x][62:31];
    }
} else {
    Rd.W[x] = 0x7fffffff;
    OV = 1;
}
for RV32: x=0
for RV64: x=1...0

```

Return value stored in long type**Parameters**

- [in] a: long type of value stored in a
- [in] b: long type of value stored in b

__STATIC_FORCEINLINE long __RV_SMMUL(long a, long b)

SMMUL (SIMD MSW Signed Multiply Word)

Type: SIMD**Syntax:**

SMMUL Rd, Rs1, Rs2
 SMMUL.u Rd, Rs1, Rs2

Purpose: Multiply the 32-bit signed integer elements of two registers and write the most significant 32-bit results to the corresponding 32-bit elements of a register. The `.u` form performs an additional rounding up operation on the multiplication results before taking the most significant 32-bit part of the results.

Description: This instruction multiplies the 32-bit elements of Rs1 with the 32-bit elements of Rs2 and writes the most significant 32-bit multiplication results to the corresponding 32-bit elements of Rd. The 32-bit elements of Rs1 and Rs2 are treated as signed integers. The `.u` form of the instruction rounds up the most significant 32-bit of the 64-bit multiplication results by adding a 1 to bit 31 of the results.

- For `smmul`/RV32 instruction, it is an alias to `mulh`/RV32 instruction.

Operations:

```
Mres[x][63:0] = Rs1.W[x] * Rs2.W[x];
if (`.u` form) {
    Round[x][32:0] = Mres[x][63:31] + 1;
    Rd.W[x] = Round[x][32:1];
} else {
    Rd.W[x] = Mres[x][63:32];
}
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Functions

```
__STATIC_FORCEINLINE long __RV_KMMAWB(long t, unsigned long a, unsigned long b)
KMMAWB (SIMD Saturating MSW Signed Multiply Word and Bottom Half and Add)
```

Type: SIMD

Syntax:

```
KMMAWB Rd, Rs1, Rs2
KMMAWB.u Rd, Rs1, Rs2
```

Purpose: Multiply the signed 32-bit integer elements of one register and the bottom 16-bit of the corresponding 32-bit elements of another register and add the most significant 32-bit results with the corresponding signed 32-bit elements of a third register. The addition result is written to the corresponding 32-bit elements of the third register. The `.u` form rounds up the multiplication results from the most significant discarded bit before the addition operations.

Description: This instruction multiplies the signed 32-bit elements of Rs1 with the signed bottom 16-bit content of the corresponding 32-bit elements of Rs2 and adds the most significant 32-bit multiplication results with the corresponding signed 32-bit elements of Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to 1. The results after saturation are written to the corresponding 32-bit elements of Rd. The `.u` form of the instruction rounds up the most significant 32-bit of the 48-bit multiplication results by adding a 1 to bit 15 of the result before the addition operations.

Operations:

```
Mres[x][47:0] = Rs1.W[x] * Rs2.W[x].H[0];
if (`.u` form) {
    Round[x][32:0] = Mres[x][47:15] + 1;
    res[x] = Rd.W[x] + Round[x][32:1];
} else {
    res[x] = Rd.W[x] + Mres[x][47:16];
}
if (res[x] > (2^31)-1) {

KMMAWT2 Rd, Rs1, Rs2
KMMAWT2.u Rd, Rs1, Rs2

```

Purpose: Multiply the signed 32-bit elements of one register and the top 16-bit of the corresponding 32-bit elements of another register, double the multiplication results and add the saturated most significant 32-bit results with the corresponding signed 32-bit elements of a third register. The saturated addition result is written to the corresponding 32-bit elements of the third register. The .u form rounds up the multiplication results from the most significant discarded bit before the addition operations.

Description: This instruction multiplies the signed 32-bit Q31 elements of Rs1 with the signed top 16-bit Q15 content of the corresponding 32-bit elements of Rs2, doubles the Q46 results to Q47 numbers and adds the saturated most significant 32-bit Q31 multiplication results with the corresponding signed 32-bit elements of Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to 1. The results after saturation are written to the corresponding 32-bit elements of Rd. The .u form of the instruction rounds up the most significant 32-bit of the 48-bit Q47 multiplication results by adding a 1 to bit 15 (i.e., bit 14 before doubling) of the result before the addition operations.

Operations:

```

if ((Rs1.W[x] == 0x80000000) & (Rs2.W[x].H[1] == 0x8000)) {
    addop.W[x] = 0x7fffffff;
    OV = 1;
} else {
    Mres[x][47:0] = Rs1.W[x] s* Rs2.W[x].H[1];
    if (`u` form) {

```

(continues on next page)

(continued from previous page)

```

    Mres[x][47:14] = Mres[x][47:14] + 1;
}
addop.W[x] = Mres[x][46:15]; // doubling
}
res[x] = Rd.W[x] + addop.W[x];
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMMWB2(long a, unsigned long b)
 KMMWB2 (SIMD Saturating MSW Signed Multiply Word and Bottom Half & 2)

Type: SIMD

Syntax:

```

KMMWB2 Rd, Rs1, Rs2
KMMWB2.u Rd, Rs1, Rs2

```

Purpose: Multiply the signed 32-bit integer elements of one register and the bottom 16-bit of the corresponding 32-bit elements of another register, double the multiplication results and write the saturated most significant 32-bit results to the corresponding 32-bit elements of a register. The `.u` form rounds up the results from the most significant discarded bit.

Description: This instruction multiplies the signed 32-bit Q31 elements of Rs1 with the signed bottom 16-bit Q15 content of the corresponding 32-bit elements of Rs2, doubles the Q46 results to Q47 numbers and writes the saturated most significant 32-bit Q31 multiplication results to the corresponding 32-bit elements of Rd. The `.u` form of the instruction rounds up the most significant 32-bit of the 48-bit Q47 multiplication results by adding a 1 to bit 15 (i.e., bit 14 before doubling) of the results.

Operations:

```

if ((Rs1.W[x] == 0x80000000) & (Rs2.W[x].H[0] == 0x8000)) {
    Rd.W[x] = 0x7fffffff;
    OV = 1;
} else {
    Mres[x][47:0] = Rs1.W[x] s* Rs2.W[x].H[0];
    if (`.u` form) {

Signed 16-bit Multiply 32-bit Add/Subtract Instructions.

there are 18 Signed 16-bit Multiply 32-bit Add/Subtract Instructions

Functions

```
__STATIC_FORCEINLINE long __RV_KMABB(long t, unsigned long a, unsigned long b)
KMABB (SIMD Saturating Signed Multiply Bottom Halves & Add)
```

Type: SIMD

Syntax:

```
KMABB Rd, Rs1, Rs2
KMABT Rd, Rs1, Rs2
KMATT Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of 32-bit elements in a register with the 16-bit content of 32-bit elements in another register and add the result to the content of 32-bit elements in the third register. The addition result may be saturated and is written to the third register.

- KMABB: $\text{rd.W}[x] + \text{bottom} * \text{bottom}$ (per 32-bit element)
- KMABT $\text{rd.W}[x] + \text{bottom} * \text{top}$ (per 32-bit element)
- KMATT $\text{rd.W}[x] + \text{top} * \text{top}$ (per 32-bit element)

Description: For the KMABB instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2. For the KMABT instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. For the KMATT instruction, it multiplies the top 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. The multiplication result is added to the content of 32-bit elements in Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq \text{Q31} \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to

1. The results after saturation are written to Rd. The 16-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[0]); // KMABB
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[1]); // KMABT
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]); // KMATT
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMABT(long t, unsigned long a, unsigned long b)
KMABT (SIMD Saturating Signed Multiply Bottom & Top Halfs & Add)

Type: SIMD

Syntax:

```
KMABB Rd, Rs1, Rs2
KMABT Rd, Rs1, Rs2
KMATT Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of 32-bit elements in a register with the 16-bit content of 32-bit elements in another register and add the result to the content of 32-bit elements in the third register. The addition result may be saturated and is written to the third register.

- KMABB: $\text{rd.W}[x] + \text{bottom} * \text{bottom}$ (per 32-bit element)
- KMABT $\text{rd.W}[x] + \text{bottom} * \text{top}$ (per 32-bit element)
- KMATT $\text{rd.W}[x] + \text{top} * \text{top}$ (per 32-bit element)

Description: For the KMABB instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2. For the KMABT instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. For the KMATT instruction, it multiplies the top 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. The multiplication result is added to the content of 32-bit elements in Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq \text{Q31} \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to

1. The results after saturation are written to Rd. The 16-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[0]); // KMABB
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[1]); // KMABT
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]); // KMATT
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMATT(long t, unsigned long a, unsigned long b)
KMATT (SIMD Saturating Signed Multiply Top Halfs & Add)

Type: SIMD

Syntax:

```
KMABB Rd, Rs1, Rs2
KMABT Rd, Rs1, Rs2
KMATT Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of 32-bit elements in a register with the 16-bit content of 32-bit elements in another register and add the result to the content of 32-bit elements in the third register. The addition result may be saturated and is written to the third register.

- KMABB: $\text{rd.W}[x] + \text{bottom} * \text{bottom}$ (per 32-bit element)
- KMABT $\text{rd.W}[x] + \text{bottom} * \text{top}$ (per 32-bit element)
- KMATT $\text{rd.W}[x] + \text{top} * \text{top}$ (per 32-bit element)

Description: For the `KMABB` instruction, it multiplies the bottom 16-bit content of 32-bit elements in `Rs1` with the bottom 16-bit content of 32-bit elements in `Rs2`. For the `KMABT` instruction, it multiplies the bottom 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2`. For the `KMATT` instruction, it multiplies the top 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2`. The multiplication result is added to the content of 32-bit elements in `Rd`. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the `OV` bit is set to

1. The results after saturation are written to `Rd`. The 16-bit contents of `Rs1` and `Rs2` are treated as signed integers.

Operations:

```
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[0]); // KMABB
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[1]); // KMABT
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]); // KMATT
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Type: SIMD

Syntax:

```
KMADA Rd, Rs1, Rs2
KMAXDA Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from 32-bit elements in two registers; and then adds the two 32-bit results and 32-bit elements in a third register together. The addition result may be saturated.

- `KMADA`: `rd.W[x] + top*top + bottom*bottom` (per 32-bit element)
- `KMAXDA`: `rd.W[x] + top*bottom + bottom*top` (per 32-bit element)

Description: For the `KMADA` instruction, it multiplies the bottom 16-bit content of 32-bit elements in `Rs1` with the bottom 16-bit content of 32-bit elements in `Rs2` and then adds the result to the result of multiplying the top 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2`. For the `KMAXDA` instruction, it multiplies the top 16-bit content of 32-bit elements in `Rs1` with the bottom 16-bit content of 32-bit elements in `Rs2` and then adds the result to the result of multiplying the bottom 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2`. The result is added to the content of 32-bit elements in `Rd`. If the addition result is beyond the Q31 number

range $(-2^{31} \leq Q31 \leq 2^{31}-1)$, it is saturated to the range and the OV bit is set to 1. The 32-bit results after saturation are written to Rd. The 16-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```
// KMADA
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]) + (Rs1.W[x].H[0] * Rs2.
↪W[x].H[0]);
// KMAXDA
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[0]) + (Rs1.W[x].H[0] * Rs2.
↪W[x].H[1]);
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1..0
```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMAXDA(long t, unsigned long a, unsigned long b)
KMAXDA (SIMD Saturating Signed Crossed Multiply Two Halfs and Two Adds)

Type: SIMD

Syntax:

```
KMADA Rd, Rs1, Rs2
KMAXDA Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from 32-bit elements in two registers; and then adds the two 32-bit results and 32-bit elements in a third register together. The addition result may be saturated.

- KMADA: $rd.W[x] + top*top + bottom*bottom$ (per 32-bit element)
- KMAXDA: $rd.W[x] + top*bottom + bottom*top$ (per 32-bit element)

Description: For the ‘KMADA instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2 and then adds the result to the result of multiplying the top 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. For the KMAXDA instruction, it multiplies the top 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2 and then adds the result to the result of multiplying the bottom 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. The result is added to the content of 32-bit elements in Rd. If the addition result is beyond the Q31 number range $(-2^{31} \leq Q31 \leq 2^{31}-1)$, it is saturated to the range and the OV bit is set to 1. The 32-bit results after saturation are written to Rd. The 16-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```

// KMADA
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]) + (Rs1.W[x].H[0] * Rs2.
↪W[x].H[0]);
// KMAXDA
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[0]) + (Rs1.W[x].H[0] * Rs2.

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMADS(long t, unsigned long a, unsigned long b)
KMADS (SIMD Saturating Signed Multiply Two Halfs & Subtract & Add)

Type: SIMD

Syntax:

```

KMADS Rd, Rs1, Rs2
KMADRS Rd, Rs1, Rs2
KMAXDS Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from 32-bit elements in two registers; and then perform a subtraction operation between the two 32-bit results. Then add the subtraction result to the corresponding 32-bit elements in a third register. The addition result may be saturated.

- KMADS: $rd.W[x] + (top * top - bottom * bottom)$ (per 32-bit element)
- KMADRS: $rd.W[x] + (bottom * bottom - top * top)$ (per 32-bit element)
- KMAXDS: $rd.W[x] + (top * bottom - bottom * top)$ (per 32-bit element)

Description: For the KMADS instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2. For the KMADRS instruction, it multiplies the top 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2. For the KMAXDS instruction, it multiplies the bottom 16-bit content of 32-bit elements in Rs1 with the top 16-bit content of 32-bit elements in Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of 32-bit elements in Rs1 with the bottom 16-bit content of 32-bit elements in Rs2. The subtraction result is then added to the content of the corresponding 32-bit elements in Rd. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV

bit is set to 1. The 32-bit results after saturation are written to Rd. The 16-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```
// KMADS
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[0]);
// KMADRS
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[0]) - (Rs1.W[x].H[1] * Rs2.
↪W[x].H[1]);
// KMAXDS
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[1]);
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t

__STATIC_FORCEINLINE long __RV_KMAXDS(long t, unsigned long a, unsigned long b)
KMAXDS (SIMD Saturating Signed Crossed Multiply Two Halfs & Subtract & Add)

Type: SIMD

Syntax:

```
KMADS Rd, Rs1, Rs2
KMADRS Rd, Rs1, Rs2
KMAXDS Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from 32-bit elements in two registers; and then perform a subtraction operation between the two 32-bit results. Then add the subtraction result to the corresponding 32-bit elements in a third register. The addition result may be saturated.

- KMADS: $rd.W[x] + (top*top - bottom*bottom)$ (per 32-bit element)
- KMADRS: $rd.W[x] + (bottom*bottom - top*top)$ (per 32-bit element)
- KMAXDS: $rd.W[x] + (top*bottom - bottom*top)$ (per 32-bit element)

Description: For the `KMADS` instruction, it multiplies the bottom 16-bit content of 32-bit elements in `Rs1` with the bottom 16-bit content of 32-bit elements in `Rs2` and then subtracts the result from the result of multiplying the top 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2`. For the `KMADRS` instruction, it multiplies the top 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2` and then subtracts the result from the result of multiplying the bottom 16-bit content of 32-bit elements in `Rs1` with the bottom 16-bit content of 32-bit elements in `Rs2`. For the `KMAXDS` instruction, it multiplies the bottom 16-bit content of 32-bit elements in `Rs1` with the top 16-bit content of 32-bit elements in `Rs2` and then subtracts the result from the result of multiplying the top 16-bit content of 32-bit elements in `Rs1` with the bottom 16-bit content of 32-bit elements in `Rs2`. The subtraction result is then added to the content of the corresponding 32-bit elements in `Rd`. If the addition result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the `OV` bit is set to 1. The 32-bit results after saturation are written to `Rd`. The 16-bit contents of `Rs1` and `Rs2` are treated as signed integers.

Operations:

```
// KMADS
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[0]);
// KMADRS
res[x] = Rd.W[x] + (Rs1.W[x].H[0] * Rs2.W[x].H[0]) - (Rs1.W[x].H[1] * Rs2.
↪W[x].H[1]);
// KMAXDS
res[x] = Rd.W[x] + (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[1]);
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] `t`: long type of value stored in `t`
- [in] `a`: unsigned long type of value stored in `a`
- [in] `b`: unsigned long type of value stored in `b`

```
__STATIC_FORCEINLINE long __RV_KMDA(unsigned long a, unsigned long b)
KMDA (SIMD Signed Multiply Two Halfs and Add)
```

Type: SIMD

Syntax:

```
KMDA Rd, Rs1, Rs2
KMXDA Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then adds the two 32-bit results together. The addition result may be saturated.

- `KMDA`: `top*top + bottom*bottom` (per 32-bit element)

- KMXDA: top*bottom + bottom*top (per 32-bit element)

Description: For the KMDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then adds the result to the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the KMXDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then adds the result to the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The addition result is checked for saturation. If saturation happens, the result is saturated to $2^{31}-1$. The final results are written to Rd. The 16-bit contents are treated as signed integers.

Operations:

```
if Rs1.W[x] != 0x80008000 or (Rs2.W[x] != 0x80008000 { // KMDA Rd.
    W[x] = Rs1.W[x].H[1] *
Rs2.W[x].H[1]) + (Rs1.W[x].H[0] * Rs2.W[x].H[0]; // KMXDA Rd.W[x] = Rs1.W[x].
H[1] * Rs2.W[x].H[0])
+ (Rs1.W[x].H[0] * Rs2.W[x].H[1]; } else { Rd.W[x] = 0x7fffffff; OV_
= 1; } for RV32: x=0 for RV64:
x=1..0
```

Return value stored in long type

+ (Rs1.W[x].H[0] * Rs2.W[x].H[1]; } else { Rd.W[x] = 0x7fffffff; OV_
↪ = 1; } for RV32: x=0 for RV64:
x=1...0

```

Return value stored in long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMSDA(long t, unsigned long a, unsigned long b)
KMSDA (SIMD Saturating Signed Multiply Two Halfs & Add & Subtract)

Type: SIMD

Syntax:

```

KMSDA Rd, Rs1, Rs2
KMSXDA Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then subtracts the two 32-bit results from the corresponding 32-bit elements of a third register. The subtraction result may be saturated.

- KMSDA: $rd.W[x] - top*top - bottom*bottom$ (per 32-bit element)
- KMSXDA: $rd.W[x] - top*bottom - bottom*top$ (per 32-bit element)

Description: For the KMSDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the KMSXDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and multiplies the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The two 32-bit multiplication results are then subtracted from the content of the corresponding 32-bit elements of Rd. If the subtraction result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to 1. The results after saturation are written to Rd. The 16-bit contents are treated as signed integers.

Operations:

```

// KMSDA
res[x] = Rd.W[x] - (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[0]);
// KMSXDA
res[x] = Rd.W[x] - (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[1]);
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0

```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_KMSXDA(long t, unsigned long a, unsigned long b)
KMSXDA (SIMD Saturating Signed Crossed Multiply Two Halfs & Add & Subtract)

Type: SIMD

Syntax:

```
KMSDA Rd, Rs1, Rs2
KMSXDA Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then subtracts the two 32-bit results from the corresponding 32-bit elements of a third register. The subtraction result may be saturated.

- KMSDA: $rd.W[x] - top * top - bottom * bottom$ (per 32-bit element)
- KMSXDA: $rd.W[x] - top * bottom - bottom * top$ (per 32-bit element)

Description: For the KMSDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the KMSXDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and multiplies the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The two 32-bit multiplication results are then subtracted from the content of the corresponding 32-bit elements of Rd. If the subtraction result is beyond the Q31 number range ($-2^{31} \leq Q31 \leq 2^{31}-1$), it is saturated to the range and the OV bit is set to 1. The results after saturation are written to Rd. The 16-bit contents are treated as signed integers.

Operations:

```
// KMSDA
res[x] = Rd.W[x] - (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[0]);
// KMSXDA
res[x] = Rd.W[x] - (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.
↪W[x].H[1]);
if (res[x] > (2^31)-1) {
    res[x] = (2^31)-1;
    OV = 1;
} else if (res[x] < -2^31) {
    res[x] = -2^31;
    OV = 1;
}
Rd.W[x] = res[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in long type

SMTT16 Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of the 32-bit elements of a register with the signed 16-bit content of the 32-bit elements of another register and write the result to a third register.

- SMBB16: $W[x].bottom * W[x].bottom$
- SMBT16: $W[x].bottom * W[x].top$
- SMTT16: $W[x].top * W[x].top$

Description: For the SMBB16 instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMBT16 instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMTT16 instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. The multiplication results are written to Rd. The 16-bit contents of Rs1 and Rs2 are treated as signed integers.

Operations:

```
Rd.W[x] = Rs1.W[x].H[0] * Rs2.W[x].H[0]; // SMBB16
Rd.W[x] = Rs1.W[x].H[0] * Rs2.W[x].H[1]; // SMBT16
Rd.W[x] = Rs1.W[x].H[1] * Rs2.W[x].H[1]; // SMTT16
for RV32: x=0,
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_SMBT16(unsigned long a, unsigned long b)
SMBT16 (SIMD Signed Multiply Bottom Half & Top Half)

Type: SIMD

Syntax:

```
SMBB16 Rd, Rs1, Rs2
SMBT16 Rd, Rs1, Rs2
SMTT16 Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of the 32-bit elements of a register with the signed 16-bit content of the 32-bit elements of another register and write the result to a third register.

- SMBB16: $W[x].bottom * W[x].bottom$

- SMBT16: $W[x].bottom * W[x].top$
- SMTT16: $W[x].top * W[x].top$

Description: For the `SMBB16` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of `Rs1` with the bottom 16-bit content of the 32-bit elements of `Rs2`. For the `SMBT16` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2`. For the `SMTT16` instruction, it multiplies the top 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2`. The multiplication results are written to `Rd`. The 16-bit contents of `Rs1` and `Rs2` are treated as signed integers.

Operations:

```
Rd.W[x] = Rs1.W[x].H[0] * Rs2.W[x].H[0]; // SMBB16
Rd.W[x] = Rs1.W[x].H[0] * Rs2.W[x].H[1]; // SMBT16
Rd.W[x] = Rs1.W[x].H[1] * Rs2.W[x].H[1]; // SMTT16
for RV32: x=0,
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] `a`: unsigned long type of value stored in `a`
- [in] `b`: unsigned long type of value stored in `b`

__STATIC_FORCEINLINE long __RV_SMTT16(unsigned long a, unsigned long b)
SMTT16 (SIMD Signed Multiply Top Half & Top Half)

Type: SIMD

Syntax:

```
SMBB16 Rd, Rs1, Rs2
SMBT16 Rd, Rs1, Rs2
SMTT16 Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of the 32-bit elements of a register with the signed 16-bit content of the 32-bit elements of another register and write the result to a third register.

- SMBB16: $W[x].bottom * W[x].bottom$
- SMBT16: $W[x].bottom * W[x].top$
- SMTT16: $W[x].top * W[x].top$

Description: For the `SMBB16` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of `Rs1` with the bottom 16-bit content of the 32-bit elements of `Rs2`. For the `SMBT16` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2`. For the `SMTT16` instruction, it multiplies the top 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2`. The multiplication results are written to `Rd`. The 16-bit contents of `Rs1` and `Rs2` are treated as signed integers.

Operations:

```
Rd.W[x] = Rs1.W[x].H[0] * Rs2.W[x].H[0]; // SMBB16
Rd.W[x] = Rs1.W[x].H[0] * Rs2.W[x].H[1]; // SMBT16
Rd.W[x] = Rs1.W[x].H[1] * Rs2.W[x].H[1]; // SMTT16
for RV32: x=0,
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_SMDS(unsigned long a, unsigned long b)
SMDS (SIMD Signed Multiply Two Halfs and Subtract)

Type: SIMD

Syntax:

```
SMDS Rd, Rs1, Rs2
SMDRS Rd, Rs1, Rs2
SMXDS Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then perform a subtraction operation between the two 32-bit results.

- SMDS: top*top - bottom*bottom (per 32-bit element)
- SMDRS: bottom*bottom - top*top (per 32-bit element)
- SMXDS: top*bottom - bottom*top (per 32-bit element)

Description: For the SMDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMDRS instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMXDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The subtraction result is written to the corresponding 32-bit element of Rd. The 16-bit contents of multiplication are treated as signed integers.

Operations:

```
* SMDS:
Rd.W[x] = (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.W[x].H[0]);
* SMDRS:
Rd.W[x] = (Rs1.W[x].H[0] * Rs2.W[x].H[0]) - (Rs1.W[x].H[1] * Rs2.W[x].H[1]);
* SMXDS:
Rd.W[x] = (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.W[x].H[1]);
```

Return value stored in long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long __RV_SMDRS(unsigned long a, unsigned long b)
SMDRS (SIMD Signed Multiply Two Halfs and Reverse Subtract)

Type: SIMD

Syntax:

```

SMDS Rd, Rs1, Rs2
SMDRS Rd, Rs1, Rs2
SMXDS Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then perform a subtraction operation between the two 32-bit results.

- SMDS: top*top - bottom*bottom (per 32-bit element)
- SMDRS: bottom*bottom - top*top (per 32-bit element)
- SMXDS: top*bottom - bottom*top (per 32-bit element)

Description: For the SMDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMDRS instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMXDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The subtraction result is written to the corresponding 32-bit element of Rd. The 16-bit contents of multiplication are treated as signed integers.

Operations:

```

* SMDS:
Rd.W[x] = (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.W[x].H[0]);
* SMDRS:
Rd.W[x] = (Rs1.W[x].H[0] * Rs2.W[x].H[0]) - (Rs1.W[x].H[1] * Rs2.W[x].H[1]);
* SMXDS:
Rd.W[x] = (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.W[x].H[1]);

```

Return value stored in long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```

__STATIC_FORCEINLINE long __RV_SMXDS(unsigned long a, unsigned long b)
    SMXDS (SIMD Signed Crossed Multiply Two Halfs and Subtract)

```

Type: SIMD

Syntax:

```

SMDS Rd, Rs1, Rs2
SMDRS Rd, Rs1, Rs2
SMXDS Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then perform a subtraction operation between the two 32-bit results.

- SMDS: top*top - bottom*bottom (per 32-bit element)
- SMDRS: bottom*bottom - top*top (per 32-bit element)
- SMXDS: top*bottom - bottom*top (per 32-bit element)

Description: For the `SMDS` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of `Rs1` with the bottom 16-bit content of the 32-bit elements of `Rs2` and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2`. For the `SMDRS` instruction, it multiplies the top 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2` and then subtracts the result from the result of multiplying the bottom 16-bit content of the 32-bit elements of `Rs1` with the bottom 16-bit content of the 32-bit elements of `Rs2`. For the `SMXDS` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of `Rs1` with the top 16-bit content of the 32-bit elements of `Rs2` and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of `Rs1` with the bottom 16-bit content of the 32-bit elements of `Rs2`. The subtraction result is written to the corresponding 32-bit element of `Rd`. The 16-bit contents of multiplication are treated as signed integers.

Operations:

```
* SMDS:
Rd.W[x] = (Rs1.W[x].H[1] * Rs2.W[x].H[1]) - (Rs1.W[x].H[0] * Rs2.W[x].H[0]);
* SMDRS:
Rd.W[x] = (Rs1.W[x].H[0] * Rs2.W[x].H[0]) - (Rs1.W[x].H[1] * Rs2.W[x].H[1]);
* SMXDS:
Rd.W[x] = (Rs1.W[x].H[1] * Rs2.W[x].H[0]) - (Rs1.W[x].H[0] * Rs2.W[x].H[1]);
```

Return value stored in long type

Parameters

- [in] `a`: unsigned long type of value stored in `a`
- [in] `b`: unsigned long type of value stored in `b`

```
__RV_SCLIP32(a, b)
```

SCLIP32 (SIMD 32-bit Signed Clip Value)

Type: DSP

Syntax:

```
SCLIP32 Rd, Rs1, imm5u[4:0]
```

Purpose: Limit the 32-bit signed integer elements of a register into a signed range simultaneously.

Description: This instruction limits the 32-bit signed integer elements stored in Rs1 into a signed integer range between $2^{\text{imm5u}}-1$ and -2^{imm5u} , and writes the limited results to Rd. For example, if imm5u is 3, the 32-bit input values should be saturated between 7 and -8. If saturation is performed, set OV bit to 1.

Operations:

```
src = Rs1.W[x];
if (src > (2^imm5u)-1) {
    src = (2^imm5u)-1;
    OV = 1;
} else if (src < -2^imm5u) {
    src = -2^imm5u;
    OV = 1;
}
Rd.W[x] = src
for RV32: x=0,
for RV64: x=1...0
```

Return value stored in long type

Parameters

- [in] a: long type of value stored in a
- [in] b: unsigned int type of value stored in b

__RV_UCLIP32 (a, b)

UCLIP32 (SIMD 32-bit Unsigned Clip Value)

Type: SIMD

Syntax:

```
UCLIP32 Rd, Rs1, imm5u[4:0]
```

Purpose: Limit the 32-bit signed integer elements of a register into an unsigned range simultaneously.

Description: This instruction limits the 32-bit signed integer elements stored in Rs1 into an unsigned integer range between $2^{\text{imm5u}}-1$ and 0, and writes the limited results to Rd. For example, if imm5u is 3, the 32-bit input values should be saturated between 7 and 0. If saturation is performed, set OV bit to 1.

Operations:

```
src = Rs1.W[x];
if (src > (2^imm5u)-1) {
    src = (2^imm5u)-1;
    OV = 1;
} else if (src < 0) {
    src = 0;
    OV = 1;
}
Rd.W[x] = src
for RV32: x=0,
for RV64: x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned int type of value stored in b

Functions

__STATIC_FORCEINLINE unsigned long __RV_CLRS32(unsigned long a)
CLRS32 (SIMD 32-bit Count Leading Redundant Sign)

Type: SIMD

Syntax:

```
CLRS32 Rd, Rs1
```

Purpose: Count the number of redundant sign bits of the 32-bit elements of a general register.

Description: Starting from the bits next to the sign bits of the 32-bit elements of Rs1, this instruction counts the number of redundant sign bits and writes the result to the corresponding 32-bit elements of Rd.

Operations:

```
snum[x] = Rs1.W[x];
cnt[x] = 0;
for (i = 30 to 0) {
    if (snum[x](i) == snum[x](31)) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.W[x] = cnt[x];
for RV32: x=0
for RV64: x=1...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_CLO32(unsigned long a)
CLO32 (SIMD 32-bit Count Leading One)

Type: SIMD

Syntax:

```
CLO32 Rd, Rs1
```

Purpose: Count the number of leading one bits of the 32-bit elements of a general register.

Description: Starting from the most significant bits of the 32-bit elements of Rs1, this instruction counts the number of leading one bits and writes the results to the corresponding 32-bit elements of Rd.

Operations:

```

snum[x] = Rs1.W[x];
cnt[x] = 0;
for (i = 31 to 0) {
    if (snum[x](i) == 1) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.W[x] = cnt[x];
for RV32: x=0
for RV64: x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_CLZ32(unsigned long a)
CLZ32 (SIMD 32-bit Count Leading Zero)

Type: SIMD

Syntax:

```
CLZ32 Rd, Rs1
```

Purpose: Count the number of leading zero bits of the 32-bit elements of a general register.

Description: Starting from the most significant bits of the 32-bit elements of Rs1, this instruction counts the number of leading zero bits and writes the results to the corresponding 32-bit elements of Rd.

Operations:

```

snum[x] = Rs1.W[x];
cnt[x] = 0;
for (i = 31 to 0) {
    if (snum[x](i) == 0) {
        cnt[x] = cnt[x] + 1;
    } else {
        break;
    }
}
Rd.W[x] = cnt[x];
for RV32: x=0
for RV64: x=1...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_PBSAD(unsigned long a, unsigned long b)
PBSAD (Parallel Byte Sum of Absolute Difference)

Type: DSP

Syntax:

```
PBSAD Rd, Rs1, Rs2
```

Purpose: Calculate the sum of absolute difference of unsigned 8-bit data elements.

Description: This instruction subtracts the un-signed 8-bit elements of Rs2 from those of Rs1. Then it adds the absolute value of each difference together and writes the result to Rd.

Operations:

```
absdiff[x] = ABS(Rs1.B[x] - Rs2.B[x]);
Rd = SUM(absdiff[x]);
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE unsigned long __RV_PBSADA(unsigned long t, unsigned long a, unsigned long b)
PBSADA (Parallel Byte Sum of Absolute Difference Accum)
```

Type: DSP

Syntax:

```
PBSADA Rd, Rs1, Rs2
```

Purpose: Calculate the sum of absolute difference of four unsigned 8-bit data elements and accumulate it into a register.

Description: This instruction subtracts the un-signed 8-bit elements of Rs2 from those of Rs1. It then adds the absolute value of each difference together along with the content of Rd and writes the accumulated result back to Rd.

Operations:

```
absdiff[x] = ABS(Rs1.B[x] - Rs2.B[x]);
Rd = Rd + SUM(absdiff[x]);
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] t: unsigned long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

8-bit Multiply with 32-bit Add Instructions

there are 3 8-bit Multiply with 32-bit Add Instructions

Functions

```
__STATIC_FORCEINLINE long __RV_SMAQA(long t, unsigned long a, unsigned long b)
SMAQA (Signed Multiply Four Bytes with 32-bit Adds)
```

Type: Partial-SIMD (Reduction)

Syntax:

```
SMAQA Rd, Rs1, Rs2
```

Purpose: Do four signed 8-bit multiplications from 32-bit chunks of two registers; and then adds the four 16-bit results and the content of corresponding 32-bit chunks of a third register together.

Description: This instruction multiplies the four signed 8-bit elements of 32-bit chunks of Rs1 with the four signed 8-bit elements of 32-bit chunks of Rs2 and then adds the four results together with the signed content of the corresponding 32-bit chunks of Rd. The final results are written back to the corresponding 32-bit chunks in Rd.

Operations:

```
res[x] = Rd.W[x] +
        (Rs1.W[x].B[3] s* Rs2.W[x].B[3]) + (Rs1.W[x].B[2] s* Rs2.W[x].B[2]) +
        (Rs1.W[x].B[1] s* Rs2.W[x].B[1]) + (Rs1.W[x].B[0] s* Rs2.W[x].B[0]);
Rd.W[x] = res[x];
for RV32: x=0,
for RV64: x=1,0
```

Return value stored in long type

Parameters

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```
__STATIC_FORCEINLINE long __RV_SMAQA_SU(long t, unsigned long a, unsigned long b)
SMAQA.SU (Signed and Unsigned Multiply Four Bytes with 32-bit Adds)
```

Type: Partial-SIMD (Reduction)

Syntax:

```
SMAQA.SU Rd, Rs1, Rs2
```

Purpose: Do four signed x unsigned 8-bit multiplications from 32-bit chunks of two registers; and then adds the four 16-bit results and the content of corresponding 32-bit chunks of a third register together.

Description: This instruction multiplies the four signed 8-bit elements of 32-bit chunks of Rs1 with the four unsigned 8-bit elements of 32-bit chunks of Rs2 and then adds the four results together with the signed content of the corresponding 32-bit chunks of Rd. The final results are written back to the corresponding 32-bit chunks in Rd.

Operations:

```

res[x] = Rd.W[x] +
    (Rs1.W[x].B[3] su* Rs2.W[x].B[3]) + (Rs1.W[x].B[2] su* Rs2.W[x].B[2]) +
    (Rs1.W[x].B[1] su* Rs2.W[x].B[1]) + (Rs1.W[x].B[0] su* Rs2.W[x].B[0]);
Rd.W[x] = res[x];
for RV32: x=0,
for RV64: x=1...0

```

Return value stored in long type**Parameters**

- [in] t: long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UMAQA(unsigned long t, unsigned long a, unsigned long b)
 UMAQA (Unsigned Multiply Four Bytes with 32-bit Adds)

Type: DSP**Syntax:**

```
UMAQA Rd, Rs1, Rs2
```

Purpose: Do four unsigned 8-bit multiplications from 32-bit chunks of two registers; and then adds the four 16-bit results and the content of corresponding 32-bit chunks of a third register together.

Description: This instruction multiplies the four unsigned 8-bit elements of 32-bit chunks of Rs1 with the four unsigned 8-bit elements of 32-bit chunks of Rs2 and then adds the four results together with the unsigned content of the corresponding 32-bit chunks of Rd. The final results are written back to the corresponding 32-bit chunks in Rd.

Operations:

```

res[x] = Rd.W[x] + (Rs1.W[x].B[3] u* Rs2.W[x].B[3]) +
    (Rs1.W[x].B[2] u* Rs2.W[x].B[2]) + (Rs1.W[x].B[1] u* Rs2.W[x].B[1]) +
    (Rs1.W[x].B[0] u* Rs2.W[x].B[0]);
Rd.W[x] = res[x];
for RV32: x=0,
for RV64: x=1...0

```

64-bit Addition & Subtraction Instructions

there are 10 64-bit Addition & Subtraction Instructions.

Functions

```

__STATIC_FORCEINLINE unsigned long long __RV_ADD64(unsigned long long a, unsigned long long b)
ADD64 (64-bit Addition)

```

Type: 64-bit Profile

Syntax:

```
ADD64 Rd, Rs1, Rs2
```

Purpose: Add two 64-bit signed or unsigned integers.

RV32 Description: This instruction adds the 64-bit integer of an even/odd pair of registers specified by Rs1(4,1) with the 64-bit integer of an even/odd pair of registers specified by Rs2(4,1), and then writes the 64-bit result to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., value d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction has the same behavior as the ADD instruction in RV64I.

Note: This instruction can be used for either signed or unsigned addition.

Operations:

```

RV32:
t_L = CONCAT(Rd(4,1), 1'b0); t_H = CONCAT(Rd(4,1), 1'b1);
a_L = CONCAT(Rs1(4,1), 1'b0); a_H = CONCAT(Rs1(4,1), 1'b1);
b_L = CONCAT(Rs2(4,1), 1'b0); b_H = CONCAT(Rs2(4,1), 1'b1);
R[t_H].R[t_L] = R[a_H].R[a_L] + R[b_H].R[b_L];
RV64:
Rd = Rs1 + Rs2;

```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE long long __RV_KADD64(long long a, long long b)
KADD64 (64-bit Signed Saturating Addition)

Type: DSP (64-bit Profile)

Syntax:

KADD64 Rd, Rs1, Rs2

Purpose: Add two 64-bit signed integers. The result is saturated to the Q63 range.

RV32 Description: This instruction adds the 64-bit signed integer of an even/odd pair of registers specified by Rs1(4,1) with the 64-bit signed integer of an even/odd pair of registers specified by Rs2(4,1). If the 64-bit result is beyond the Q63 number range ($-2^{63} \leq Q63 \leq 2^{63}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., value d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction adds the 64-bit signed integer in Rs1 with the 64-bit signed integer in Rs2. If the result is beyond the Q63 number range ($-2^{63} \leq Q63 \leq 2^{63}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is written to Rd.

Operations:

<pre> RV32: t_L = CONCAT(Rd(4,1), 1'b0); t_H = CONCAT(Rd(4,1), 1'b1); a_L = CONCAT(Rs1(4,1), 1'b0); a_H = CONCAT(Rs1(4,1), 1'b1); b_L = CONCAT(Rs2(4,1), 1'b0); b_H = CONCAT(Rs2(4,1), 1'b1); result = R[a_H].R[a_L] + R[b_H].R[b_L]; if (result > (2^63)-1) { result = (2^63)-1; OV = 1; } else if (result < -2^63) { result = -2^63; OV = 1; } R[t_H].R[t_L] = result; RV64: result = Rs1 + Rs2; if (result > (2^63)-1) { result = (2^63)-1; OV = 1; } else if (result < -2^63) { result = -2^63; OV = 1; } Rd = result; </pre>

Return value stored in long long type

Parameters

- [in] a: long long type of value stored in a
- [in] b: long long type of value stored in b

__STATIC_FORCEINLINE long long __RV_KSUB64(long long a, long long b)
 KSUB64 (64-bit Signed Saturating Subtraction)

Type: DSP (64-bit Profile)

Syntax:

```
KSUB64 Rd, Rs1, Rs2
```

Purpose: Perform a 64-bit signed integer subtraction. The result is saturated to the Q63 range.

RV32 Description: This instruction subtracts the 64-bit signed integer of an even/odd pair of registers specified by Rs2(4,1) from the 64-bit signed integer of an even/odd pair of registers specified by Rs1(4,1). If the 64-bit result is beyond the Q63 number range ($-2^{63} \leq Q63 \leq 2^{63}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is then written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: This instruction subtracts the 64-bit signed integer of Rs2 from the 64-bit signed integer of Rs1. If the 64-bit result is beyond the Q63 number range ($-2^{63} \leq Q63 \leq 2^{63}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is then written to Rd.

Operations:

```
RV32:
t_L = CONCAT(Rd(4,1), 1'b0); t_H = CONCAT(Rd(4,1), 1'b1);
a_L = CONCAT(Rs1(4,1), 1'b0); a_H = CONCAT(Rs1(4,1), 1'b1);
b_L = CONCAT(Rs2(4,1), 1'b0); b_H = CONCAT(Rs2(4,1), 1'b1);
result = R[a_H].R[a_L] - R[b_H].R[b_L];
if (result > (2^63)-1) {
    result = (2^63)-1; OV = 1;
} else if (result < -2^63) {
    result = -2^63; OV = 1;
}
R[t_H].R[t_L] = result;
RV64:
result = Rs1 - Rs2;
if (result > (2^63)-1) {
    result = (2^63)-1; OV = 1;
} else if (result < -2^63) {
    result = -2^63; OV = 1;
}
Rd = result;
```

Return value stored in long long type

Parameters

- [in] a: long long type of value stored in a
- [in] b: long long type of value stored in b

__STATIC_FORCEINLINE long long __RV_RADD64(long long a, long long b)
 RADD64 (64-bit Signed Halving Addition)

Type: DSP (64-bit Profile)

Syntax:

```
RADD64 Rd, Rs1, Rs2
```

Purpose: Add two 64-bit signed integers. The result is halved to avoid overflow or saturation.

RV32 Description: This instruction adds the 64-bit signed integer of an even/odd pair of registers specified by Rs1(4,1) with the 64-bit signed integer of an even/odd pair of registers specified by Rs2(4,1). The 64-bit addition result is first arithmetically right-shifted by 1 bit and then written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., value d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction adds the 64-bit signed integer in Rs1 with the 64-bit signed integer in Rs2. The 64-bit addition result is first arithmetically right-shifted by 1 bit and then written to Rd.

Operations:

```
RV32:
t_L = CONCAT(Rd(4,1), 1'b0); t_H = CONCAT(Rd(4,1), 1'b1);
a_L = CONCAT(Rs1(4,1), 1'b0); a_H = CONCAT(Rs1(4,1), 1'b1);
b_L = CONCAT(Rs2(4,1), 1'b0); b_H = CONCAT(Rs2(4,1), 1'b1);
R[t_H].R[t_L] = (R[a_H].R[a_L] + R[b_H].R[b_L]) s>> 1;
RV64:
Rd = (Rs1 + Rs2) s>> 1;
```

Return value stored in long long type

Parameters

- [in] a: long long type of value stored in a
- [in] b: long long type of value stored in b

```
__STATIC_FORCEINLINE long long __RV_RSUB64(long long a, long long b)
RSUB64 (64-bit Signed Halving Subtraction)
```

Type: DSP (64-bit Profile)

Syntax:

```
RSUB64 Rd, Rs1, Rs2
```

Purpose: Perform a 64-bit signed integer subtraction. The result is halved to avoid overflow or saturation.

RV32 Description: This instruction subtracts the 64-bit signed integer of an even/odd pair of registers specified by Rb(4,1) from the 64-bit signed integer of an even/odd pair of registers specified by Ra(4,1). The subtraction result is first arithmetically right-shifted by 1 bit and then written to an even/odd pair of registers specified by Rt(4,1). Rx(4,1), i.e., value d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction subtracts the 64-bit signed integer in Rs2 from the 64-bit signed integer in Rs1. The 64-bit subtraction result is first arithmetically right-shifted by 1 bit and then written to Rd.

Operations:

```
RV32:
t_L = CONCAT(Rd(4,1), 1'b0); t_H = CONCAT(Rd(4,1), 1'b1);
a_L = CONCAT(Rs1(4,1), 1'b0); a_H = CONCAT(Rs1(4,1), 1'b1);
b_L = CONCAT(Rs2(4,1), 1'b0); b_H = CONCAT(Rs2(4,1), 1'b1);
```

(continues on next page)

(continued from previous page)

```

R[t_H].R[t_L] = (R[a_H].R[a_L] - R[b_H].R[b_L]) s>> 1;
RV64:
Rd = (Rs1 - Rs2) s>> 1;

```

Return value stored in long long type

Parameters

- [in] a: long long type of value stored in a
- [in] b: long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_SUB64(unsigned long long a, unsigned long long b)
SUB64 (64-bit Subtraction)

Type: DSP (64-bit Profile)

Syntax:

```
SUB64 Rd, Rs1, Rs2
```

Purpose: Perform a 64-bit signed or unsigned integer subtraction.

RV32 Description: This instruction subtracts the 64-bit integer of an even/odd pair of registers specified by Rs2(4,1) from the 64-bit integer of an even/odd pair of registers specified by Rs1(4,1), and then writes the 64-bit result to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: This instruction subtracts the 64-bit integer of Rs2 from the 64-bit integer of Rs1, and then writes the 64-bit result to Rd.

Note: This instruction can be used for either signed or unsigned subtraction.

Operations:

```

* RV32:
t_L = CONCAT(Rd(4,1), 1'b0); t_H = CONCAT(Rd(4,1), 1'b1);
a_L = CONCAT(Rs1(4,1), 1'b0); a_H = CONCAT(Rs1(4,1), 1'b1);
b_L = CONCAT(Rs2(4,1), 1'b0); b_H = CONCAT(Rs2(4,1), 1'b1);
R[t_H].R[t_L] = R[a_H].R[a_L] - R[b_H].R[b_L];
* RV64:
Rd = Rs1 - Rs2;

```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_UKADD64(unsigned long long a, unsigned long long b)
UKADD64 (64-bit Unsigned Saturating Addition)

Type: DSP (64-bit Profile)

Syntax:

```
UKADD64 Rd, Rs1, Rs2
```

Purpose: Add two 64-bit unsigned integers. The result is saturated to the U64 range.

RV32 Description: This instruction adds the 64-bit unsigned integer of an even/odd pair of registers specified by Rs1(4,1) with the 64-bit unsigned integer of an even/odd pair of registers specified by Rs2(4,1). If the 64-bit result is beyond the U64 number range ($0 \leq U64 \leq 2^{64}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction adds the 64-bit unsigned integer in Rs1 with the 64-bit unsigned integer in Rs2. If the 64-bit result is beyond the U64 number range ($0 \leq U64 \leq 2^{64}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is written to Rd.

Operations:

```
* RV32:
t_L = CONCAT(Rt(4,1), 1'b0); t_H = CONCAT(Rt(4,1), 1'b1);
a_L = CONCAT(Ra(4,1), 1'b0); a_H = CONCAT(Ra(4,1), 1'b1);
b_L = CONCAT(Rb(4,1), 1'b0); b_H = CONCAT(Rb(4,1), 1'b1);
result = R[a_H].R[a_L] + R[b_H].R[b_L];
if (result > (2^64)-1) {
    result = (2^64)-1; OV = 1;
}
R[t_H].R[t_L] = result;
* RV64:
result = Rs1 + Rs2;
if (result > (2^64)-1) {
    result = (2^64)-1; OV = 1;
}
Rd = result;
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_UKSUB64(unsigned long long a, unsigned long long b)
UKSUB64 (64-bit Unsigned Saturating Subtraction)

Type: DSP (64-bit Profile)

Syntax:

```
UKSUB64 Rd, Rs1, Rs2
```

Purpose: Perform a 64-bit signed integer subtraction. The result is saturated to the U64 range.

RV32 Description: This instruction subtracts the 64-bit unsigned integer of an even/odd pair of registers specified by Rs2(4,1) from the 64-bit unsigned integer of an even/odd pair of registers specified by Rs1(4,1). If the 64-bit result is beyond the U64 number range ($0 \leq U64 \leq 2^{64}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is then written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: This instruction subtracts the 64-bit unsigned integer of Rs2 from the 64-bit unsigned integer of an even/odd pair of Rs1. If the 64-bit result is beyond the U64 number range ($0 \leq U64 \leq 2^{64}-1$), it is saturated to the range and the OV bit is set to 1. The saturated result is then written to Rd.

Operations:

```
* RV32:
t_L = CONCAT(Rd(4,1),1'b0); t_H = CONCAT(Rd(4,1),1'b1);
a_L = CONCAT(Rs1(4,1),1'b0); a_H = CONCAT(Rs1(4,1),1'b1);
b_L = CONCAT(Rs2(4,1),1'b0); b_H = CONCAT(Rs2(4,1),1'b1);
result = R[a_H].R[a_L] - R[b_H].R[b_L];
if (result < 0) {
    result = 0; OV = 1;
}
R[t_H].R[t_L] = result;
* RV64
result = Rs1 - Rs2;
if (result < 0) {
    result = 0; OV = 1;
}
Rd = result;
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_URADD64(unsigned long long a, unsigned long long b)
URADD64 (64-bit Unsigned Halving Addition)

Type: DSP (64-bit Profile)

Syntax:

```
URADD64 Rd, Rs1, Rs2
```

Purpose: Add two 64-bit unsigned integers. The result is halved to avoid overflow or saturation.

RV32 Description: This instruction adds the 64-bit unsigned integer of an even/odd pair of registers specified by Rs1(4,1) with the 64-bit unsigned integer of an even/odd pair of registers specified by Rs2(4,1). The 64-bit addition result is first logically right-shifted by 1 bit and then written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction adds the 64-bit unsigned integer in Rs1 with the 64-bit unsigned integer Rs2. The 64-bit addition result is first logically right-shifted by 1 bit and then written to Rd.

Operations:

```
* RV32:
t_L = CONCAT(Rt(4,1),1'b0); t_H = CONCAT(Rt(4,1),1'b1);
a_L = CONCAT(Ra(4,1),1'b0); a_H = CONCAT(Ra(4,1),1'b1);
b_L = CONCAT(Rb(4,1),1'b0); b_H = CONCAT(Rb(4,1),1'b1);
R[t_H].R[t_L] = (R[a_H].R[a_L] + R[b_H].R[b_L]) u>> 1;
* RV64:
Rd = (Rs1 + Rs2) u>> 1;
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_URSUB64(unsigned long long a, unsigned long long b)
URSUB64 (64-bit Unsigned Halving Subtraction)

Type: DSP (64-bit Profile)

Syntax:

```
URSUB64 Rd, Rs1, Rs2
```

Purpose: Perform a 64-bit unsigned integer subtraction. The result is halved to avoid overflow or saturation.

RV32 Description: This instruction subtracts the 64-bit unsigned integer of an even/odd pair of registers specified by Rs2(4,1) from the 64-bit unsigned integer of an even/odd pair of registers specified by Rs1(4,1). The subtraction result is first logically right-shifted by 1 bit and then written to an even/odd pair of registers specified by Rd(4,1). Rx(4,1), i.e., d, determines the even/odd pair group of two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: This instruction subtracts the 64-bit unsigned integer in Rs2 from the 64-bit unsigned integer in Rs1. The subtraction result is first logically right-shifted by 1 bit and then written to Rd.

Operations:

```
* RV32:
t_L = CONCAT(Rt(4,1), 1'b0); t_H = CONCAT(Rt(4,1), 1'b1);
a_L = CONCAT(Ra(4,1), 1'b0); a_H = CONCAT(Ra(4,1), 1'b1);
b_L = CONCAT(Rb(4,1), 1'b0); b_H = CONCAT(Rb(4,1), 1'b1);
R[t_H].R[t_L] = (R[a_H].R[a_L] - R[b_H].R[b_L]) u>> 1;
* RV64:
Rd = (Rs1 - Rs2) u>> 1;
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

```

group **NMSIS_Core_DSP_Intrinsic_SIMD_8B_ADDSUB**

SIMD 8-bit Addition & Subtraction Instructions.

Based on the types of the four 8-bit arithmetic operations, the SIMD 8-bit add/subtract instructions can be classified into 2 main categories: Addition (four 8-bit addition), and Subtraction (four 8-bit subtraction). Based on the way of how an overflow condition is handled for signed or unsigned operation, the SIMD 8-bit add/subtract instructions can be classified into 5 groups: Wrap-around (dropping overflow), Signed Halving (keeping overflow by dropping 1 LSB bit), Unsigned Halving, Signed Saturation (clipping overflow), and Unsigned Saturation. Together, there are 10 SIMD 8-bit add/subtract instructions.

Functions

```

__STATIC_FORCEINLINE unsigned long __RV_ADD8(unsigned long a, unsigned long b)
    ADD8 (SIMD 8-bit Addition)

```

Type: SIMD

Syntax:

```
ADD8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit integer element additions simultaneously.

Description: This instruction adds the 8-bit integer elements in Rs1 with the 8-bit integer elements in Rs2, and then writes the 8-bit element results to Rd.

Note: This instruction can be used for either signed or unsigned addition.

Operations:

```

Rd.B[x] = Rs1.B[x] + Rs2.B[x];
for RV32: x=3...0,
for RV64: x=7...0

```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

```

__STATIC_FORCEINLINE unsigned long __RV_KADD8(unsigned long a, unsigned long b)
    KADD8 (SIMD 8-bit Signed Saturating Addition)

```

Type: SIMD

Syntax:

```
KADD8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer element saturating additions simultaneously.

Description: This instruction adds the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2. If any of the results are beyond the Q7 number range ($-2^7 \leq Q7 \leq 2^7-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.B[x] + Rs2.B[x];
if (res[x] > 127) {
    res[x] = 127;
    OV = 1;
} else if (res[x] < -128) {
    res[x] = -128;
    OV = 1;
}
Rd.B[x] = res[x];
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_KSUB8(unsigned long a, unsigned long b)
 KSUB8 (SIMD 8-bit Signed Saturating Subtraction)

Type: SIMD

Syntax:

```
KSUB8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed elements saturating subtractions simultaneously.

Description: This instruction subtracts the 8-bit signed integer elements in Rs2 from the 8-bit signed integer elements in Rs1. If any of the results are beyond the Q7 number range ($-2^7 \leq Q7 \leq 2^7-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.B[x] - Rs2.B[x];
if (res[x] > (2^7)-1) {
    res[x] = (2^7)-1;
    OV = 1;
} else if (res[x] < -2^7) {
    res[x] = -2^7;
    OV = 1;
}
Rd.B[x] = res[x];
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RADD8(unsigned long a, unsigned long b)
RADD8 (SIMD 8-bit Signed Halving Addition)

Type: SIMD

Syntax:

```
RADD8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer element additions simultaneously. The element results are halved to avoid overflow or saturation.

Description: This instruction adds the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2. The results are first arithmetically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Rs1 = 0x7F, Rs2 = 0x7F, Rd = 0x7F
* Rs1 = 0x80, Rs2 = 0x80, Rd = 0x80
* Rs1 = 0x40, Rs2 = 0x80, Rd = 0xE0
```

Operations:

```
Rd.B[x] = (Rs1.B[x] + Rs2.B[x]) s>> 1; for RV32: x=3...0, for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_RSUB8(unsigned long a, unsigned long b)
RSUB8 (SIMD 8-bit Signed Halving Subtraction)

Type: SIMD

Syntax:

```
RSUB8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit signed integer element subtractions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 8-bit signed integer elements in Rs2 from the 8-bit signed integer elements in Rs1. The results are first arithmetically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Rs1 = 0x7F, Rs2 = 0x80, Rd = 0x7F
* Rs1 = 0x80, Rs2 = 0x7F, Rd = 0x80
* Rs1 = 0x80, Rs2 = 0x40, Rd = 0xA0
```

Operations:

```
Rd.B[x] = (Rs1.B[x] - Rs2.B[x]) s>> 1;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_SUB8(unsigned long a, unsigned long b)
SUB8 (SIMD 8-bit Subtraction)

Type: SIMD

Syntax:

```
SUB8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit integer element subtractions simultaneously.

Description: This instruction subtracts the 8-bit integer elements in Rs2 from the 8-bit integer elements in Rs1, and then writes the result to Rd.

Note: This instruction can be used for either signed or unsigned subtraction.

Operations:

```
Rd.B[x] = Rs1.B[x] - Rs2.B[x];
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKADD8(unsigned long a, unsigned long b)
UKADD8 (SIMD 8-bit Unsigned Saturating Addition)

Type: SIMD

Syntax:

```
UKADD8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer element saturating additions simultaneously.

Description: This instruction adds the 8-bit unsigned integer elements in Rs1 with the 8-bit unsigned integer elements in Rs2. If any of the results are beyond the 8-bit unsigned number range ($0 \leq \text{RES} \leq 28-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.B[x] + Rs2.B[x];
if (res[x] > (2^8)-1) {
    res[x] = (2^8)-1;
    OV = 1;
}
Rd.B[x] = res[x];
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_UKSUB8(unsigned long a, unsigned long b)
UKSUB8 (SIMD 8-bit Unsigned Saturating Subtraction)

Type: SIMD

Syntax:

```
UKSUB8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer elements saturating subtractions simultaneously.

Description: This instruction subtracts the 8-bit unsigned integer elements in Rs2 from the 8-bit unsigned integer elements in Rs1. If any of the results are beyond the 8-bit unsigned number range ($0 \leq \text{RES} \leq 28-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.B[x] - Rs2.B[x];
if (res[x] < 0) {
    res[x] = 0;
    OV = 1;
}
Rd.B[x] = res[x];
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URADD8(unsigned long a, unsigned long b)
URADD8 (SIMD 8-bit Unsigned Halving Addition)

Type: SIMD

Syntax:

```
URADD8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer element additions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction adds the 8-bit unsigned integer elements in Rs1 with the 8-bit unsigned integer elements in Rs2. The results are first logically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Ra = 0x7F, Rb = 0x7F, Rt = 0x7F
* Ra = 0x80, Rb = 0x80, Rt = 0x80
* Ra = 0x40, Rb = 0x80, Rt = 0x60
```

Operations:

```
Rd.B[x] = (Rs1.B[x] + Rs2.B[x]) u>> 1;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_URSUB8(unsigned long a, unsigned long b)
 URSUB8 (SIMD 8-bit Unsigned Halving Subtraction)

Type: SIMD

Syntax:

```
URSUB8 Rd, Rs1, Rs2
```

Purpose: Do 8-bit unsigned integer element subtractions simultaneously. The results are halved to avoid overflow or saturation.

Description: This instruction subtracts the 8-bit unsigned integer elements in Rs2 from the 8-bit unsigned integer elements in Rs1. The results are first logically right-shifted by 1 bit and then written to Rd.

Examples:

```
* Ra = 0x7F, Rb = 0x80 Rt = 0xFF
* Ra = 0x80, Rb = 0x7F Rt = 0x00
* Ra = 0x80, Rb = 0x40 Rt = 0x20
```

Operations:

```
Rd.B[x] = (Rs1.B[x] - Rs2.B[x]) u>> 1;
for RV32: x=3...0,
for RV64: x=7...0
```

Return value stored in unsigned long type

Parameters

Functions

```

__STATIC_FORCEINLINE long long __RV_SMAL(long long a, unsigned long b)
    SMAL (Signed Multiply Halfs & Add 64-bit)

```

Type: Partial-SIMD

Syntax:

SMAL Rd, Rs1, Rs2

Purpose: Multiply the signed bottom 16-bit content of the 32-bit elements of a register with the top 16-bit content of the same 32-bit elements of the same register, and add the results with a 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to another even/odd pair of registers (RV32) or a register (RV64).

RV32 Description: This instruction multiplies the bottom 16-bit content of the lower 32-bit of Rs2 with the top 16-bit content of the lower 32-bit of Rs2 and adds the result with the 64-bit value of an even/odd pair of registers specified by Rs1(4,1). The 64-bit addition result is written back to an even/odd pair of registers specified by Rd(4,1). The 16-bit values of Rs2, and the 64-bit value of the Rs1(4,1) register- pair are treated as signed integers. Rx(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: This instruction multiplies the bottom 16-bit content of the 32-bit elements of Rs2 with the top 16-bit content of the same 32-bit elements of Rs2 and adds the results with the 64-bit value of Rs1. The 64-bit addition result is written back to Rd. The 16-bit values of Rs2, and the 64-bit value of Rs1 are treated as signed integers.

Operations:

RV32: Mres[31:0] = Rs2.H[1] * Rs2.H[0]; Idx0 = CONCAT(Rs1(4,1),1'b0); Idx1 = CONCAT(Rs1(4,1),1'b1); + Idx2 = CONCAT(Rd(4,1),1'b0); Idx3 = CONCAT(Rd(4,1),1'b1); R[Idx3].R[Idx2] = R[Idx1].R[Idx0] + SE64(Mres[31:0]); RV64: Mres[0][31:0] = Rs2.W[0].H[1] * Rs2.W[0].H[0]; Mres[1][31:0] = Rs2.W[1].H[1] * Rs2.W[1].H[0]; Rd = Rs1 + SE64(Mres[1][31:0]) + SE64(Mres[0][31:0]);

Return value stored in long long type

Parameters

- [in] a: long long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALBB(long long t, unsigned long a, unsigned long b)
 SMALBB (Signed Multiply Bottom Halfs & Add 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```
SMALBB Rd, Rs1, Rs2
SMALBT Rd, Rs1, Rs2
SMALTT Rd, Rs1, Rs2
```

Purpose: Multiply the signed 16-bit content of the 32-bit elements of a register with the 16-bit content of the corresponding 32-bit elements of another register and add the results with a 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to the register-pair (RV32) or the register (RV64).

- SMALBB: rt pair + bottom*bottom (all 32-bit elements)
- SMALBT rt pair + bottom*top (all 32-bit elements)
- SMALTT rt pair + top*top (all 32-bit elements)

RV32 Description: For the SMALBB instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2. For the SMALBT instruction, it multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMALTT instruction, it multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2. The multiplication result is added with the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the SMALBB instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMALBT instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMALTT instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. The multiplication results are added with the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
RV32:
Mres[31:0] = Rs1.H[0] * Rs2.H[0]; // SMALBB
Mres[31:0] = Rs1.H[0] * Rs2.H[1]; // SMALBT
Mres[31:0] = Rs1.H[1] * Rs2.H[1]; // SMALTT
Idx0 = CONCAT(Rd(4,1), 1'b0); Idx1 = CONCAT(Rd(4,1), 1'b1);
R[Idx1].R[Idx0] = R[Idx1].R[Idx0] + SE64(Mres[31:0]);
RV64:
// SMALBB
Mres[0][31:0] = Rs1.W[0].H[0] * Rs2.W[0].H[0];
Mres[1][31:0] = Rs1.W[1].H[0] * Rs2.W[1].H[0];
// SMALBT
Mres[0][31:0] = Rs1.W[0].H[0] * Rs2.W[0].H[1];
```

(continued from previous page)

```

Mres[1][31:0] = Rs1.W[1].H[0] * Rs2.W[1].H[1];
// SMALTT
Mres[0][31:0] = Rs1.W[0].H[1] * Rs2.W[0].H[1];
Mres[1][31:0] = Rs1.W[1].H[1] * Rs2.W[1].H[1];
Rd = Rd + SE64(Mres[0][31:0]) + SE64(Mres[1][31:0]);

```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALBT(long long t, unsigned long a, unsigned long b)
SMALBT (Signed Multiply Bottom Half & Top Half & Add 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```

SMALBB Rd, Rs1, Rs2
SMALBT Rd, Rs1, Rs2
SMALTT Rd, Rs1, Rs2

```

Purpose: Multiply the signed 16-bit content of the 32-bit elements of a register with the 16-bit content of the corresponding 32-bit elements of another register and add the results with a 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to the register-pair (RV32) or the register (RV64).

- SMALBB: rt pair + bottom*bottom (all 32-bit elements)
- SMALBT rt pair + bottom*top (all 32-bit elements)
- SMALTT rt pair + top*top (all 32-bit elements)

RV32 Description: For the SMALBB instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2. For the SMALBT instruction, it multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMALTT instruction, it multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2. The multiplication result is added with the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the SMALBB instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMALBT instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMALTT instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. The multiplication results are added with the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```

RV32:
Mres[31:0] = Rs1.H[0] * Rs2.H[0]; // SMALBB
Mres[31:0] = Rs1.H[0] * Rs2.H[1]; // SMALBT

Rd = Rd + SE64(Mres[0][31:0]) + SE64(Mres[1][31:0]);

```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALTT(long long t, unsigned long a, unsigned long b)
 SMALTT (Signed Multiply Top Halfs & Add 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```

SMALBB Rd, Rs1, Rs2
SMALBT Rd, Rs1, Rs2
SMALTT Rd, Rs1, Rs2

```

Purpose: Multiply the signed 16-bit content of the 32-bit elements of a register with the 16-bit content of the corresponding 32-bit elements of another register and add the results with a 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to the register-pair (RV32) or the register (RV64).

- SMALBB: rt pair + bottom*bottom (all 32-bit elements)
- SMALBT rt pair + bottom*top (all 32-bit elements)
- SMALTT rt pair + top*top (all 32-bit elements)

RV32 Description: For the SMALBB instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2. For the SMALBT instruction, it multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMALTT instruction, it multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2. The multiplication result is added with the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the `SMALBB` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the `SMALBT` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the `SMALTT` instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. The multiplication results are added with the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
RV32:
Mres[31:0] = Rs1.H[0] * Rs2.H[0]; // SMALBB
Mres[31:0] = Rs1.H[0] * Rs2.H[1]; // SMALBT
Mres[31:0] = Rs1.H[1] * Rs2.H[1]; // SMALTT
Idx0 = CONCAT(Rd(4,1), 1'b0); Idx1 = CONCAT(Rd(4,1), 1'b1);
R[Idx1].R[Idx0] = R[Idx1].R[Idx0] + SE64(Mres[31:0]);
RV64:
// SMALBB
Mres[0][31:0] = Rs1.W[0].H[0] * Rs2.W[0].H[0];
Mres[1][31:0] = Rs1.W[1].H[0] * Rs2.W[1].H[0];
// SMALBT
Mres[0][31:0] = Rs1.W[0].H[0] * Rs2.W[0].H[1];
Mres[1][31:0] = Rs1.W[1].H[0] * Rs2.W[1].H[1];
// SMALTT
Mres[0][31:0] = Rs1.W[0].H[1] * Rs2.W[0].H[1];
Mres[1][31:0] = Rs1.W[1].H[1] * Rs2.W[1].H[1];
Rd = Rd + SE64(Mres[0][31:0]) + SE64(Mres[1][31:0]);
```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALDA(long long t, unsigned long a, unsigned long b)
SMALDA (Signed Multiply Two Halfs and Two Adds 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```
SMALDA Rd, Rs1, Rs2
SMALXDA Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then adds the two 32-bit results and the 64-bit value of an even/odd pair of registers together.

- SMALDA: rt pair+ top*top + bottom*bottom (all 32-bit elements)
- SMALXDA: rt pair+ top*bottom + bottom*top (all 32-bit elements)

RV32 Description: For the `SMALDA` instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then adds the result to the result of multiplying the top 16-bit content of Rs1 with the top 16-bit content of Rs2 with unlimited precision. For the `SMALXDA` instruction, it multiplies the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then adds the result to the result of multiplying the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2 with unlimited precision. The result is added to the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit

addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the SMALDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then adds the result to the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 with unlimited precision. For the SMALXDA instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then adds the result to the result of multiplying the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 with unlimited precision. The results are added to the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
RV32:
// SMALDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[0]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[1]);
// SMALXDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[1]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[0]);
Idx0 = CONCAT(Rd(4,1), 1'b0); Idx1 = CONCAT(Rd(4,1), 1'b1);
R[Idx1].R[Idx0] = R[Idx1].R[Idx0] + SE64(Mres0[31:0]) + SE64(Mres1[31:0]);
RV64:
// SMALDA
Mres0[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[0]);
Mres1[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[1]);
Mres0[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[1].H[0]);
Mres1[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[1].H[1]);
// SMALXDA
Mres0[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[1]);
Mres1[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[0]);
Mres0[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[1].H[1]);
Mres1[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[1].H[0]);
Rd = Rd + SE64(Mres0[0][31:0]) + SE64(Mres1[0][31:0]) + SE64(Mres0[1][31:0]) +
SE64(Mres1[1][31:0]);
```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALXDA(long long t, unsigned long a, unsigned long b)
SMALXDA (Signed Crossed Multiply Two Halves and Two Adds 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```
SMALDA Rd, Rs1, Rs2
SMALXDA Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then adds the two 32-bit results and the 64-bit value of an even/odd pair of registers together.

- SMALDA: $rt\ pair + top * top + bottom * bottom$ (all 32-bit elements)
- SMALXDA: $rt\ pair + top * bottom + bottom * top$ (all 32-bit elements)

RV32 Description: For the SMALDA instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then adds the result to the result of multiplying the top 16-bit content of Rs1 with the top 16-bit content of Rs2 with unlimited precision. For the SMALXDA instruction, it multiplies the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then adds the result to the result of multiplying the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2 with unlimited precision. The result is added to the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the SMALDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then adds the result to the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 with unlimited precision. For the SMALXDA instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then adds the result to the result of multiplying the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 with unlimited precision. The results are added to the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
RV32:
// SMALDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[0]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[1]);
// SMALXDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[1]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[0]);
Idx0 = CONCAT(Rd(4,1), 1'b0); Idx1 = CONCAT(Rd(4,1), 1'b1);
R[Idx1].R[Idx0] = R[Idx1].R[Idx0] + SE64(Mres0[31:0]) + SE64(Mres1[31:0]);
RV64:
// SMALDA
Mres0[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[0]);
Mres1[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[1]);
Mres0[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[1].H[0]);
Mres1[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[1].H[1]);
// SMALXDA
Mres0[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[1]);
Mres1[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[0]);
Mres0[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[1].H[1]);
Mres1[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[1].H[0]);
Rd = Rd + SE64(Mres0[0][31:0]) + SE64(Mres1[0][31:0]) + SE64(Mres0[1][31:0]) + SE64(Mres1[1][31:0]);
```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t

- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALDS(long long t, unsigned long a, unsigned long b)
SMALDS (Signed Multiply Two Halfs & Subtract & Add 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```
SMALDS Rd, Rs1, Rs2
SMALDRS Rd, Rs1, Rs2
SMALXDS Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then perform a subtraction operation between the two 32-bit results. Then add the subtraction result to the 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to the register-pair.

- SMALDS: $rt\ pair + (top * top - bottom * bottom)$ (all 32-bit elements)
- SMALDRS: $rt\ pair + (bottom * bottom - top * top)$ (all 32-bit elements)
- SMALXDS: $rt\ pair + (top * bottom - bottom * top)$ (all 32-bit elements)

RV32 Description: For the SMALDS instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMALDRS instruction, it multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2. For the SMALXDS instruction, it multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2. The subtraction result is then added to the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the SMALDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMALDRS instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMALXDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The subtraction results are then added to the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
* RV32:
Mres[31:0] = (Rs1.H[1] * Rs2.H[1]) - (Rs1.H[0] * Rs2.H[0]); // SMALDS
Mres[31:0] = (Rs1.H[0] * Rs2.H[0]) - (Rs1.H[1] * Rs2.H[1]); // SMALDRS
Mres[31:0] = (Rs1.H[1] * Rs2.H[0]) - (Rs1.H[0] * Rs2.H[1]); // SMALXDS
```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMALDRS(long long t, unsigned long a, unsigned long b)
 SMALDRS (Signed Multiply Two Halfs & Reverse Subtract & Add 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```

SMALDS Rd, Rs1, Rs2
SMALDRS Rd, Rs1, Rs2
SMALXDS Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then perform a subtraction operation between the two 32-bit results. Then add the subtraction result to the 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to the register-pair.

- SMALDS: rt pair + (top*top - bottom*bottom) (all 32-bit elements)
- SMALDRS: rt pair + (bottom*bottom - top*top) (all 32-bit elements)
- SMALXDS: rt pair + (top*bottom - bottom*top) (all 32-bit elements)

RV32 Description: For the SMALDS instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMALDRS instruction, it multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2. For the SMALXDS instruction, it multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2. The subtraction result is then added to the 64-bit value of an even/odd pair of registers

specified by $Rd(4,1)$. The 64-bit addition result is written back to the register-pair. The 16-bit values of $Rs1$ and $Rs2$, and the 64-bit value of the register-pair are treated as signed integers. $Rd(4,1)$, i.e., d , determines the even/odd pair group of the two registers. Specifically, the register pair includes register $2d$ and $2d+1$. The odd $2d+1$ register of the pair contains the high 32-bit of the operand and the even $2d$ register of the pair contains the low 32-bit of the operand.

RV64 Description: For the `SMALDS` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of $Rs1$ with the bottom 16-bit content of the 32-bit elements of $Rs2$ and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of $Rs1$ with the top 16-bit content of the 32-bit elements of $Rs2$. For the `SMALDRS` instruction, it multiplies the top 16-bit content of the 32-bit elements of $Rs1$ with the top 16-bit content of the 32-bit elements of $Rs2$ and then subtracts the result from the result of multiplying the bottom 16-bit content of the 32-bit elements of $Rs1$ with the bottom 16-bit content of the 32-bit elements of $Rs2$. For the `SMALXDS` instruction, it multiplies the bottom 16-bit content of the 32-bit elements of $Rs1$ with the top 16-bit content of the 32-bit elements of $Rs2$ and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of $Rs1$ with the bottom 16-bit content of the 32-bit elements of $Rs2$. The subtraction results are then added to the 64-bit value of Rd . The 64-bit addition result is written back to Rd . The 16-bit values of $Rs1$ and $Rs2$, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
* RV32:
Mres[31:0] = (Rs1.H[1] * Rs2.H[1]) - (Rs1.H[0] * Rs2.H[0]); // SMALDS
Mres[31:0] = (Rs1.H[0] * Rs2.H[0]) - (Rs1.H[1] * Rs2.H[1]); // SMALDRS
Mres[31:0] = (Rs1.H[1] * Rs2.H[0]) - (Rs1.H[0] * Rs2.H[1]); // SMALXDS
Idx0 = CONCAT(Rd(4,1), 1'b0); Idx1 = CONCAT(Rd(4,1), 1'b1);
R[Idx1].R[Idx0] = R[Idx1].R[Idx0] + SE64(Mres[31:0]);

* RV64:
// SMALDS
Mres[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[1]) - (Rs1.W[0].H[0] * Rs2.W[0].
↪H[0]);
Mres[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[0].H[1]) - (Rs1.W[1].H[0] * Rs2.W[1].
↪H[0]);
// SMALDRS
Mres[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[0]) - (Rs1.W[0].H[1] * Rs2.W[0].
↪H[1]);
Mres[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[0].H[0]) - (Rs1.W[1].H[1] * Rs2.W[1].
↪H[1]);
// SMALXDS
Mres[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[0]) - (Rs1.W[0].H[0] * Rs2.W[0].
↪H[1]);
Mres[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[0].H[0]) - (Rs1.W[1].H[0] * Rs2.W[1].
↪H[1]);

```

Return value stored in long long type

Parameters

- [in] t : long long type of value stored in t
- [in] a : unsigned long type of value stored in a
- [in] b : unsigned long type of value stored in b

`__STATIC_FORCEINLINE long long __RV_SMALXDS(long long t, unsigned long a, unsigned long b)`
SMALXDS (Signed Crossed Multiply Two Halfs & Subtract & Add 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```
SMALDS Rd, Rs1, Rs2
SMALDRS Rd, Rs1, Rs2
SMALXDS Rd, Rs1, Rs2
```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then perform a subtraction operation between the two 32-bit results. Then add the subtraction result to the 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The addition result is written back to the register-pair.

- SMALDS: $rt\ pair + (top * top - bottom * bottom)$ (all 32-bit elements)
- SMALDRS: $rt\ pair + (bottom * bottom - top * top)$ (all 32-bit elements)
- SMALXDS: $rt\ pair + (top * bottom - bottom * top)$ (all 32-bit elements)

RV32 Description: For the SMALDS instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMALDRS instruction, it multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2. For the SMALXDS instruction, it multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2. The subtraction result is then added to the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit addition result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the operand and the even 2d register of the pair contains the low 32-bit of the operand.

RV64 Description: For the SMALDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMALDRS instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. For the SMALXDS instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2 and then subtracts the result from the result of multiplying the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2. The subtraction results are then added to the 64-bit value of Rd. The 64-bit addition result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
* RV32:
Mres[31:0] = (Rs1.H[1] * Rs2.H[1]) - (Rs1.H[0] * Rs2.H[0]); // SMALDS

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMSLDA(long long t, unsigned long a, unsigned long b)
 SMSLDA (Signed Multiply Two Halfs & Add & Subtract 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```

SMSLDA Rd, Rs1, Rs2
SMSLXDA Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then subtracts the two 32-bit results from the 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The subtraction result is written back to the register-pair.

- SMSLDA: rd pair - top*top - bottom*bottom (all 32-bit elements)
- SMSLXDA: rd pair - top*bottom - bottom*top (all 32-bit elements)

RV32 Description: For the SMSLDA instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMSLXDA instruction, it multiplies the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2. The two multiplication results are subtracted from the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit subtraction result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The odd 2d+1 register of the pair contains the high 32-bit of the result and the even 2d register of the pair contains the low 32-bit of the result.

RV64 Description: For the SMSLDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMSLXDA instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. The four multiplication results are subtracted from the 64-bit value of Rd. The 64-bit subtraction result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```

* RV32:
// SMSLDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[0]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[1]);
// SMSLXDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[1]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[0]);
Idx0 = CONCAT(Rd(4,1), 1'b0); Idx1 = CONCAT(Rd(4,1), 1'b1);
R[Idx1].R[Idx0] = R[Idx1].R[Idx0] - SE64(Mres0[31:0]) - SE64(Mres1[31:0]);
* RV64:
// SMSLDA
Mres0[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[0]);
Mres1[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[1]);
Mres0[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[1].H[0]);
Mres1[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[1].H[1]);
// SMSLXDA
Mres0[0][31:0] = (Rs1.W[0].H[0] * Rs2.W[0].H[1]);
Mres1[0][31:0] = (Rs1.W[0].H[1] * Rs2.W[0].H[0]);
Mres0[1][31:0] = (Rs1.W[1].H[0] * Rs2.W[1].H[1]);
Mres1[1][31:0] = (Rs1.W[1].H[1] * Rs2.W[1].H[0]);
Rd = Rd - SE64(Mres0[0][31:0]) - SE64(Mres1[0][31:0]) - SE64(Mres0[1][31:0]) -
SE64(Mres1[1][31:0]);

```

Return value stored in long long type

Parameters

- [in] t: long long type of value stored in t
- [in] a: unsigned long type of value stored in a
- [in] b: unsigned long type of value stored in b

__STATIC_FORCEINLINE long long __RV_SMSLXDA(long long t, unsigned long a, unsigned long b)
 SMSLXDA (Signed Crossed Multiply Two Halves & Add & Subtract 64-bit)

Type: DSP (64-bit Profile)

Syntax:

```

SMSLDA Rd, Rs1, Rs2
SMSLXDA Rd, Rs1, Rs2

```

Purpose: Do two signed 16-bit multiplications from the 32-bit elements of two registers; and then subtracts the two 32-bit results from the 64-bit value of an even/odd pair of registers (RV32) or a register (RV64). The subtraction result is written back to the register-pair.

- SMSLDA: rd pair - top*top - bottom*bottom (all 32-bit elements)
- SMSLXDA: rd pair - top*bottom - bottom*top (all 32-bit elements)

RV32 Description: For the SMSLDA instruction, it multiplies the bottom 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and multiplies the top 16-bit content of Rs1 with the top 16-bit content of Rs2. For the SMSLXDA instruction, it multiplies the top 16-bit content of Rs1 with the bottom 16-bit content of Rs2 and multiplies the bottom 16-bit content of Rs1 with the top 16-bit content of Rs2. The two multiplication results are subtracted from the 64-bit value of an even/odd pair of registers specified by Rd(4,1). The 64-bit subtraction result is written back to the register-pair. The 16-bit values of Rs1 and Rs2, and the 64-bit value of the register-pair are treated as signed integers. Rd(4,1), i.e., d, determines the even/odd pair group of the two registers. Specifically, the register pair includes register 2d and 2d+1. The

odd $2d+1$ register of the pair contains the high 32-bit of the result and the even $2d$ register of the pair contains the low 32-bit of the result.

RV64 Description: For the SMSLDA instruction, it multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and multiplies the top 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. For the SMSLXDA instruction, it multiplies the top 16-bit content of the 32-bit elements of Rs1 with the bottom 16-bit content of the 32-bit elements of Rs2 and multiplies the bottom 16-bit content of the 32-bit elements of Rs1 with the top 16-bit content of the 32-bit elements of Rs2. The four multiplication results are subtracted from the 64-bit value of Rd. The 64-bit subtraction result is written back to Rd. The 16-bit values of Rs1 and Rs2, and the 64-bit value of Rd are treated as signed integers.

Operations:

```
* RV32:
// SMSLDA
Mres0[31:0] = (Rs1.H[0] * Rs2.H[0]);
Mres1[31:0] = (Rs1.H[1] * Rs2.H[1]);
// SMSLXDA

Functions

```

__STATIC_FORCEINLINE unsigned long long __RV_DKHM8(unsigned long long a, unsigned long long b)
DKHM8 (64-bit SIMD Signed Saturating Q7 Multiply)

```

Type: SIMD

Syntax:

```

DKHM8 Rd, Rs1, Rs2
# Rd, Rs1, Rs2 are all even/odd pair of registers

```

Purpose: Do Q7xQ7 element multiplications simultaneously. The Q14 results are then reduced to Q7 numbers again.

Description: For the DKHM8 instruction, multiply the top 8-bit Q7 content of 16-bit chunks in Rs1 with the top 8-bit Q7 content of 16-bit chunks in Rs2. At the same time, multiply the bottom 8-bit Q7 content of 16-bit chunks in Rs1 with the bottom 8-bit Q7 content of 16-bit chunks in Rs2.

The Q14 results are then right-shifted 7-bits and saturated into Q7 values. The Q7 results are then written into Rd. When both the two Q7 inputs of a multiplication are 0x80, saturation will happen. The result will be saturated to 0x7F and the overflow flag OV will be set.

Operations:

```

op1t = Rs1.B[x+1]; op2t = Rs2.B[x+1]; // top
op1b = Rs1.B[x]; op2b = Rs2.B[x]; // bottom
for ((aop,bop,res) in [(op1t,op2t,rest), (op1b,op2b,resb)]) {
    if (0x80 != aop | 0x80 != bop) {
        res = (aop s* bop) >> 7;
    } else {
        res= 0x7F;
        OV = 1;
    }
}
Rd.H[x/2] = concat(rest, resb);
for RV32, x=0,2,4,6

```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKHM16(unsigned long long a, unsigned long long b)
DKHM16 (64-bit SIMD Signed Saturating Q15 Multiply)

Type: SIMD

Syntax:

```
DKHM16 Rd, Rs1, Rs2
# Rd, Rs1, Rs2 are all even/odd pair of registers
```

Purpose: Do Q15xQ15 element multiplications simultaneously. The Q30 results are then reduced to Q15 numbers again.

Description: For the DKHM16 instruction, multiply the top 16-bit Q15 content of 32-bit chunks in Rs1 with the top 16-bit Q15 content of 32-bit chunks in Rs2. At the same time, multiply the bottom 16-bit Q15 content of 32-bit chunks in Rs1 with the bottom 16-bit Q15 content of 32-bit chunks in Rs2.

The Q30 results are then right-shifted 15-bits and saturated into Q15 values. The Q15 results are then written into Rd. When both the two Q15 inputs of a multiplication are 0x8000, saturation will happen. The result will be saturated to 0x7FFF and the overflow flag OV will be set.

Operations:

```
op1t = Rs1.H[x+1]; op2t = Rs2.H[x+1]; // top
op1b = Rs1.H[x]; op2b = Rs2.H[x]; // bottom
for ((aop,bop,res) in [(op1t,op2t,rest), (op1b,op2b,resb)]) {
    if (0x8000 != aop | 0x8000 != bop) {
        res = (aop s* bop) >> 15;
    } else {
        res= 0x7FFF;
        OV = 1;
    }
}
Rd.W[x/2] = concat(rest, resb);
for RV32: x=0, 2
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKABS8(unsigned long long a)
DKABS8 (64-bit SIMD 8-bit Saturating Absolute)

Type: SIMD

Syntax:

```
DKABS8 Rd, Rs1
# Rd, Rs1 are all even/odd pair of registers
```

Purpose: Get the absolute value of 8-bit signed integer elements simultaneously.

Description: This instruction calculates the absolute value of 8-bit signed integer elements stored in Rs1 and writes the element results to Rd. If the input number is 0x80, this instruction generates 0x7f as the output and sets the OV bit to 1.

Operations:

```
src = Rs1.B[x];
if (src == 0x80) {
    src = 0x7f;
    OV = 1;
} else if (src[7] == 1)
    src = -src;
Rd.B[x] = src;
for RV32: x=7...0,
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a

__STATIC_FORCEINLINE unsigned long long __RV_DKABS16(unsigned long long a)
DKABS16 (64-bit SIMD 16-bit Saturating Absolute)

Type: SIMD

Syntax:

```
DKABS16 Rd, Rs1
# Rd, Rs1 are all even/odd pair of registers
```

Purpose: Get the absolute value of 16-bit signed integer elements simultaneously.

Description: This instruction calculates the absolute value of 16-bit signed integer elements stored in Rs1 and writes the element results to Rd. If the input number is 0x8000, this instruction generates 0x7fff as the output and sets the OV bit to 1.

Operations:

```
src = Rs1.H[x];
if (src == 0x8000) {
    src = 0x7fff;
    OV = 1;
} else if (src[15] == 1)
    src = -src;
Rd.H[x] = src;
for RV32: x=3...0,
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a

__STATIC_FORCEINLINE unsigned long long __RV_DKSLRA8(unsigned long long a, int b)
DKSLRA8 (64-bit SIMD 8-bit Shift Left Logical with Saturation or Shift Right Arithmetic)

Type: SIMD

Syntax:

```
DKSLRA8 Rd, Rs1, Rs2
# Rd, Rs1 are all even/odd pair of registers
```

Purpose: Do 8-bit elements logical left (positive) or arithmetic right (negative) shift operation with Q7 saturation for the left shift.

Description: The 8-bit data elements of Rs1 are left-shifted logically or right-shifted arithmetically based on the value of Rs2[3:0]. Rs2[3:0] is in the signed range of $[-2^3, 2^3-1]$. A positive Rs2[3:0] means logical left shift and a negative Rs2[3:0] means arithmetic right shift. The shift amount is the absolute value of Rs2[3:0]. However, the behavior of $Rs2[3:0] == -2^3$ (0x8) is defined to be equivalent to the behavior of $Rs2[3:0] == -(2^3-1)$ (0x9). The left-shifted results are saturated to the 8-bit signed integer range of $[-2^7, 2^7-1]$. If any saturation happens, this instruction sets the OV flag. The value of Rs2[31:4] will not affect this instruction.

Operations:

```
if (Rs2[3:0] < 0) {
    sa = -Rs2[3:0];
    sa = (sa == 8)? 7 : sa;
    Rd.B[x] = SE8(Rs1.B[x][7:sa]);
} else {
    sa = Rs2[2:0];
    res[(7+sa):0] = Rs1.B[x] <<(logic) sa;
    if (res > (2^7)-1) {
        res[7:0] = 0x7f; OV = 1;
    } else if (res < -2^7) {
        res[7:0] = 0x80; OV = 1;
    }
    Rd.B[x] = res[7:0];
}
for RV32: x=7...0,
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKSLRA16(unsigned long long a, int b)
DKSLRA16 (64-bit SIMD 16-bit Shift Left Logical with Saturation or Shift Right Arithmetic)

Type: SIMD

Syntax:

```
DKSLRA16 Rd, Rs1, Rs2
# Rd, Rs1 are all even/odd pair of registers
```

Purpose: Do 16-bit elements logical left (positive) or arithmetic right (negative) shift operation with Q15 saturation for the left shift.

Description: The 16-bit data elements of Rs1 are left-shifted logically or right-shifted arithmetically based on the value of Rs2[4:0]. Rs2[4:0] is in the signed range of $[-2^4, 2^4-1]$. A positive Rs2[4:0] means logical left shift and a negative Rs2[4:0] means arithmetic right shift. The shift amount is the absolute value of Rs2[4:0]. However, the behavior of $Rs2[4:0] == -2^4$ (0x10) is defined to be equivalent to the behavior of $Rs2[4:0] == -(2^4-1)$ (0x11). The left-shifted results are saturated to the 16-bit

signed integer range of $[-2^{15}, 2^{15}-1]$. After the shift, saturation, or rounding, the final results are written to Rd. If any saturation happens, this instruction sets the OV flag. The value of Rs2[31:5] will not affect this instruction.

Operations:

```
if (Rs2[4:0] < 0) {
    sa = -Rs2[4:0];
    sa = (sa == 16)? 15 : sa;
    Rd.H[x] = SE16(Rs1.H[x][15:sa]);
} else {
    sa = Rs2[3:0];
    res[(15+sa):0] = Rs1.H[x] <<(logic) sa;
    if (res > (2^15)-1) {
        res[15:0] = 0x7fff; OV = 1;
    } else if (res < -2^15) {
        res[15:0] = 0x8000; OV = 1;
    }
    d.H[x] = res[15:0];
}
for RV32: x=3...0,
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: int type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKADD8(unsigned long long a, unsigned long long b)
DKADD8 (64-bit SIMD 8-bit Signed Saturating Addition)

Type: SIMD

Syntax:

```
DKADD8 Rd, Rs1, Rs2
# Rd, Rs1, Rs2 are all even/odd pair of registers
```

Purpose: Do 8-bit signed integer element saturating additions simultaneously.

Description: This instruction adds the 8-bit signed integer elements in Rs1 with the 8-bit signed integer elements in Rs2. If any of the results are beyond the Q7 number range ($-2^7 \leq Q7 \leq 2^7-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.B[x] + Rs2.B[x];
if (res[x] > 127) {
    res[x] = 127;
    OV = 1;
} else if (res[x] < -128) {
    res[x] = -128;
    OV = 1;
}
Rd.B[x] = res[x];
for RV32: x=7...0,
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKADD16(unsigned long long a, unsigned long long b)
 DKADD16 (64-bit SIMD 16-bit Signed Saturating Addition)

Type: SIMD

Syntax:

```
DKADD16 Rd, Rs1, Rs2
# Rd, Rs1, Rs2 are all even/odd pair of registers
```

Purpose: Do 16-bit signed integer element saturating additions simultaneously.

Description: This instruction adds the 16-bit signed integer elements in Rs1 with the 16-bit signed integer elements in Rs2. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```
res[x] = Rs1.H[x] + Rs2.H[x];
if (res[x] > 32767) {
    res[x] = 32767;
    OV = 1;
} else if (res[x] < -32768) {
    res[x] = -32768;
    OV = 1;
}
Rd.H[x] = res[x];
for RV32: x=3...0,
```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKSUB8(unsigned long long a, unsigned long long b)
 DKSUB8 (64-bit SIMD 8-bit Signed Saturating Subtraction)

Type: SIMD

Syntax:

```
DKSUB8 Rd, Rs1, Rs2
# Rd, Rs1, Rs2 are all even/odd pair of registers
```

Purpose: Do 8-bit signed elements saturating subtractions simultaneously.

Description: This instruction subtracts the 8-bit signed integer elements in Rs2 from the 8-bit signed integer elements in Rs1. If any of the results are beyond the Q7 number range ($-2^7 \leq Q7 \leq 2^7-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```

res[x] = Rs1.B[x] - Rs2.B[x];
if (res[x] > (2^7)-1) {
    res[x] = (2^7)-1;
    OV = 1;
} else if (res[x] < -2^7) {
    res[x] = -2^7;
    OV = 1;
}
Rd.B[x] = res[x];
for RV32: x=7...0,

```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long long __RV_DKSUB16(unsigned long long a, unsigned long long b)
 DKSUB16 (64-bit SIMD 16-bit Signed Saturating Subtraction)

Type: SIMD

Syntax:

```

DKSUB16 Rd, Rs1, Rs2
# Rd, Rs1, Rs2 are all even/odd pair of registers

```

Purpose: Do 16-bit signed integer elements saturating subtractions simultaneously.

Description: This instruction subtracts the 16-bit signed integer elements in Rs2 from the 16-bit signed integer elements in Rs1. If any of the results are beyond the Q15 number range ($-2^{15} \leq Q15 \leq 2^{15}-1$), they are saturated to the range and the OV bit is set to 1. The saturated results are written to Rd.

Operations:

```

res[x] = Rs1.H[x] - Rs2.H[x];
if (res[x] > (2^15)-1) {
    res[x] = (2^15)-1;
    OV = 1;
} else if (res[x] < -2^15) {
    res[x] = -2^15;
    OV = 1;
}
Rd.H[x] = res[x];
for RV32: x=3...0,

```

Return value stored in unsigned long long type

Parameters

- [in] a: unsigned long long type of value stored in a
- [in] b: unsigned long long type of value stored in b

__STATIC_FORCEINLINE unsigned long __RV_EXPD80(unsigned long a)
 EXPD80 (Expand and Copy Byte 0 to 32bit)

Type: DSP

Syntax:

```
EXPD80 Rd, Rs1
```

Purpose: Copy 8-bit data from 32-bit chunks into 4 bytes in a register.

Description: Moves Rs1.B[0][7:0] to Rd.[0][7:0], Rd.[1][7:0], Rd.[2][7:0], Rd.[3][7:0]

Operations:

```
Rd.W[x][31:0] = CONCAT(Rs1.B[0][7:0], Rs1.B[0][7:0], Rs1.B[0][7:0], Rs1.
↳B[0][7:0]);
for RV32: x=0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

```
__STATIC_FORCEINLINE unsigned long __RV_EXPD81(unsigned long a)
EXPD81 (Expand and Copy Byte 1 to 32bit)
```

Type: DSP

Syntax:

```
EXPD81 Rd, Rs1
```

Purpose: Copy 8-bit data from 32-bit chunks into 4 bytes in a register.

Description: Moves Rs1.B[1][7:0] to Rd.[0][7:0], Rd.[1][7:0], Rd.[2][7:0], Rd.[3][7:0]

Operations:

```
Rd.W[x][31:0] = CONCAT(Rs1.B[1][7:0], Rs1.B[1][7:0], Rs1.B[1][7:0], Rs1.
↳B[1][7:0]);
for RV32: x=0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

```
__STATIC_FORCEINLINE unsigned long __RV_EXPD82(unsigned long a)
EXPD82 (Expand and Copy Byte 2 to 32bit)
```

Type: DSP

Syntax:

```
EXPD82 Rd, Rs1
```

Purpose: Copy 8-bit data from 32-bit chunks into 4 bytes in a register.

Description: Moves Rs1.B[2][7:0] to Rd.[0][7:0], Rd.[1][7:0], Rd.[2][7:0], Rd.[3][7:0]

Operations:

```
Rd.W[x][31:0] = CONCAT(Rs1.B[2][7:0], Rs1.B[2][7:0], Rs1.B[2][7:0], Rs1.
↳B[2][7:0]);
for RV32: x=0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

__STATIC_FORCEINLINE unsigned long __RV_EXP83(unsigned long a)

EXP83 (Expand and Copy Byte 3 to 32bit)

Type: DSP

Syntax:

```
EXP83 Rd, Rs1
```

Purpose: Copy 8-bit data from 32-bit chunks into 4 bytes in a register.

Description: Moves Rs1.B[3][7:0] to Rd.[0][7:0], Rd.[1][7:0], Rd.[2][7:0], Rd.[3][7:0]

Operations:

```
Rd.W[x][31:0] = CONCAT(Rs1.B[3][7:0], Rs1.B[3][7:0], Rs1.B[3][7:0], Rs1.
↪B[3][7:0]);
for RV32: x=0
```

Return value stored in unsigned long type

Parameters

- [in] a: unsigned long type of value stored in a

group **NMSIS_Core_DSP_Intrinsic**

Functions that generate RISC-V DSP SIMD instructions.

The following functions generate specified RISC-V SIMD instructions that cannot be directly accessed by compiler.

- **DSP ISA Extension Instruction Summary**

- **Shorthand Definitions**

- * r.H == r.H1: r[31:16], r.L == r.H0: r[15:0]
- * r.B3: r[31:24], r.B2: r[23:16], r.B1: r[15:8], r.B0: r[7:0]
- * r.B[x]: r[(x*8+7):(x*8+0)]
- * r.H[x]: r[(x*16+7):(x*16+0)]
- * r.W[x]: r[(x*32+31):(x*32+0)]
- * r[xU]: the upper 32-bit of a 64-bit number; xU represents the GPR number that contains this upper part 32-bit value.
- * r[xL]: the lower 32-bit of a 64-bit number; xL represents the GPR number that contains this lower part 32-bit value.
- * r[xU].r[xL]: a 64-bit number that is formed from a pair of GPRs.
- * s>>: signed arithmetic right shift:
- * u>>: unsigned logical right shift
- * SAT.Qn(): Saturate to the range of $[-2^n, 2^n-1]$, if saturation happens, set PSW.OV.
- * SAT.Um(): Saturate to the range of $[0, 2^m-1]$, if saturation happens, set PSW.OV.

- * RUND(): Indicate rounding, i.e., add 1 to the most significant discarded bit for right shift or MSW-type multiplication instructions.
- * Sign or Zero Extending functions:
 - SEm(data): Sign-Extend data to m-bit.
 - ZEm(data): Zero-Extend data to m-bit.
- * ABS(x): Calculate the absolute value of x.
- * CONCAT(x,y): Concatenate x and y to form a value.
- * u<: Unsinged less than comparison.
- * u<=: Unsinged less than & equal comparison.
- * u>: Unsinged greater than comparison.
- * s*: Signed multiplication.
- * u*: Unsigned multiplication.

2.5.8 Peripheral Access

`__I` volatile const

`__O` volatile

`__IO` volatile

`__IM` volatile const

`__OM` volatile

`__IOM` volatile

`_VAL2FLD` (field, value) (((uint32_t)(value) << field ## _Pos) & field ## _Msk)

`_FLD2VAL` (field, value) (((uint32_t)(value) & field ## _Msk) >> field ## _Pos)

group **NMSIS_Core_PeriphAccess**

Naming conventions and optional features for accessing peripherals.

The section below describes the naming conventions, requirements, and optional features for accessing device specific peripherals. Most of the rules also apply to the core peripherals.

The **Device Header File <device.h>** contains typically these definition and also includes the core specific header files.

Defines

`__I` volatile const

Defines 'read only' permissions.

`__O` volatile

Defines 'write only' permissions.

`__IO` volatile

Defines 'read / write' permissions.

`__IM` volatile const

Defines 'read only' structure member permissions.

__OM volatile

Defines 'write only' structure member permissions.

__IOM volatile

Defines 'read/write' structure member permissions.

_VAL2FLD (field, value) (((uint32_t)(value) << field ## _Pos) & field ## _Msk)

Mask and shift a bit field value for use in a register bit range.

The macro `_VAL2FLD` uses the `#define`'s `_Pos` and `_Msk` of the related bit field to shift bit-field values for assigning to a register.

Example:

```
ECLIC->CFG = _VAL2FLD(CLIC_CLICCFG_NLBIT, 3);
```

Return Masked and shifted value.

Parameters

- [in] `field`: Name of the register bit field.
- [in] `value`: Value of the bit field. This parameter is interpreted as an `uint32_t` type.

_FLD2VAL (field, value) (((uint32_t)(value) & field ## _Msk) >> field ## _Pos)

Mask and shift a register value to extract a bit field value.

The macro `_FLD2VAL` uses the `#define`'s `_Pos` and `_Msk` of the related bit field to extract the value of a bit field from a register.

Example:

```
nlbits = _FLD2VAL(CLIC_CLICCFG_NLBIT, ECLIC->CFG);
```

Return Masked and shifted bit field value.

Parameters

- [in] `field`: Name of the register bit field.
- [in] `value`: Value of register. This parameter is interpreted as an `uint32_t` type.

2.5.9 SysTick Timer(SysTimer)

Click [Nuclei Timer Unit](#)¹⁷ to learn about Core Timer Unit in Nuclei ISA Spec.

SysTimer API

__STATIC_FORCEINLINE void SysTimer_SetLoadValue(uint64_t value)

__STATIC_FORCEINLINE uint64_t SysTimer_GetLoadValue(void)

__STATIC_FORCEINLINE void SysTimer_SetCompareValue(uint64_t value)

__STATIC_FORCEINLINE uint64_t SysTimer_GetCompareValue(void)

__STATIC_FORCEINLINE void SysTimer_Start(void)

__STATIC_FORCEINLINE void SysTimer_Stop(void)

¹⁷ https://doc.nucleisys.com/nuclei_spec/isa/timer.html

```

__STATIC_FORCEINLINE void SysTimer_SetControlValue(uint32_t mctl)
__STATIC_FORCEINLINE uint32_t SysTimer_GetControlValue(void)
__STATIC_FORCEINLINE void SysTimer_SetSWIRQ(void)
__STATIC_FORCEINLINE void SysTimer_ClearSWIRQ(void)
__STATIC_FORCEINLINE uint32_t SysTimer_GetMsipValue(void)
__STATIC_FORCEINLINE void SysTimer_SetMsipValue(uint32_t msip)
__STATIC_FORCEINLINE void SysTimer_SoftwareReset(void)
__STATIC_INLINE uint32_t SysTick_Config(uint64_t ticks)
__STATIC_FORCEINLINE uint32_t SysTick_Reload(uint64_t ticks)

```

group **NMSIS_Core_SysTimer**

Functions that configure the Core System Timer.

Functions

```
__STATIC_FORCEINLINE void SysTimer_SetLoadValue(uint64_t value)
```

Set system timer load value.

This function set the system timer load value in MTIMER register.

Remark

- Load value is 64bits wide.
- SysTimer_GetLoadValue

Parameters

- [in] value: value to set system timer MTIMER register.

```
__STATIC_FORCEINLINE uint64_t SysTimer_GetLoadValue(void)
```

Get system timer load value.

This function get the system timer current value in MTIMER register.

Return current value(64bit) of system timer MTIMER register.

Remark

- Load value is 64bits wide.
- SysTimer_SetLoadValue

```
__STATIC_FORCEINLINE void SysTimer_SetCompareValue(uint64_t value)
```

Set system timer compare value.

This function set the system Timer compare value in MTIMERCMP register.

Remark

- Compare value is 64bits wide.
- If compare value is larger than current value timer interrupt generate.
- Modify the load value or compare value less to clear the interrupt.
- SysTimer_GetCompareValue

Parameters

- [in] value: compare value to set system timer MTIMERCMP register.

__STATIC_FORCEINLINE uint64_t SysTimer_GetCompareValue(void)
Get system timer compare value.

This function get the system timer compare value in MTIMERCMP register.

Return compare value of system timer MTIMERCMP register.

Remark

- Compare value is 64bits wide.
- SysTimer_SetCompareValue

__STATIC_FORCEINLINE void SysTimer_Start(void)
Enable system timer counter running.

Enable system timer counter running by clear TIMESTOP bit in MTIMECTL register.

__STATIC_FORCEINLINE void SysTimer_Stop(void)
Stop system timer counter running.

Stop system timer counter running by set TIMESTOP bit in MTIMECTL register.

__STATIC_FORCEINLINE void SysTimer_SetControlValue(uint32_t mctl)
Set system timer control value.

This function set the system timer MTIMECTL register value.

Remark

- Bit TIMESTOP is used to start and stop timer. Clear TIMESTOP bit to 0 to start timer, otherwise to stop timer.
- Bit CMPCLREN is used to enable auto MTIMER clear to zero when MTIMER >= MTIMER-CMP. Clear CMPCLREN bit to 0 to stop auto clear MTIMER feature, otherwise to enable it.
- Bit CLKSRC is used to select timer clock source. Clear CLKSRC bit to 0 to use *mtime_toggle_a*, otherwise use *core_clk_aon*
- SysTimer_GetControlValue

Parameters

- [in] mctl: value to set MTIMECTL register

__STATIC_FORCEINLINE uint32_t SysTimer_GetControlValue(void)
Get system timer control value.

This function get the system timer MTIMECTL register value.

Return MTIMECTL register value

Remark

- SysTimer_SetControlValue

__STATIC_FORCEINLINE void SysTimer_SetSWIRQ(void)
Trigger or set software interrupt via system timer.

This function set the system timer MSIP bit in MSIP register.

Remark

- Set system timer MSIP bit and generate a SW interrupt.
- SysTimer_ClearSWIRQ

- SysTimer_GetMsipValue

__STATIC_FORCEINLINE void SysTimer_ClearSWIRQ(void)

Clear system timer software interrupt pending request.

This function clear the system timer MSIP bit in MSIP register.

Remark

- Clear system timer MSIP bit in MSIP register to clear the software interrupt pending.
- SysTimer_SetSWIRQ
- SysTimer_GetMsipValue

__STATIC_FORCEINLINE uint32_t SysTimer_GetMsipValue(void)

Get system timer MSIP register value.

This function get the system timer MSIP register value.

Return Value of Timer MSIP register.

Remark

- Bit0 is SW interrupt flag. Bit0 is 1 then SW interrupt set. Bit0 is 0 then SW interrupt clear.
- SysTimer_SetSWIRQ
- SysTimer_ClearSWIRQ

__STATIC_FORCEINLINE void SysTimer_SetMsipValue(uint32_t msip)

Set system timer MSIP register value.

This function set the system timer MSIP register value.

Parameters

- [in] msip: value to set MSIP register

__STATIC_FORCEINLINE void SysTimer_SoftwareReset(void)

Do software reset request.

This function will do software reset request through MTIMER

- Software need to write *SysTimer_MSFRST_KEY* (page 86) to generate software reset request
- The software request flag can be cleared by reset operation to clear

Remark

- The software reset is sent to SoC, SoC need to generate reset signal and send back to Core
- This function will not return, it will do while(1) to wait the Core reset happened

__STATIC_INLINE uint32_t SysTick_Config(uint64_t ticks)

System Tick Configuration.

Initializes the System Timer and its non-vector interrupt, and starts the System Tick Timer.

In our default implementation, the timer counter will be set to zero, and it will start a timer compare non-vector interrupt when it matches the ticks user set, during the timer interrupt user should reload the system tick using SysTick_Reload function or similar function written by user, so it can produce period timer interrupt.

Return 0 Function succeeded.

Return 1 Function failed.

Remark

- For [__NUCLEI_N_REV](#) (page 58) $\geq 0x0104$, the CMPCLREN bit in MTIMECTL is introduced, but we assume that the CMPCLREN bit is set to 0, so MTIMER register will not be auto cleared to 0 when MTIMER \geq MTIMERCMP.
- When the variable __Vendor_SysTickConfig is set to 1, then the function SysTick_Config is not included.
- In this case, the file **<Device>.h** must contain a vendor-specific implementation of this function.
- If user need this function to start a period timer interrupt, then in timer interrupt handler routine code, user should call SysTick_Reload with ticks to reload the timer.
- This function only available when __SYSTIMER_PRESENT == 1 and __ECLIC_PRESENT == 1 and __Vendor_SysTickConfig == 0

See

- SysTimer_SetCompareValue; SysTimer_SetLoadValue

Parameters

- [in] ticks: Number of ticks between two interrupts.

__STATIC_FORCEINLINE uint32_t SysTick_Reload(uint64_t ticks)

System Tick Reload.

Reload the System Timer Tick when the MTIMECMP reached TIME value

Return 0 Function succeeded.

Return 1 Function failed.

Remark

- For [__NUCLEI_N_REV](#) (page 58) $\geq 0x0104$, the CMPCLREN bit in MTIMECTL is introduced, but for this SysTick_Config function, we assume this CMPCLREN bit is set to 0, so in interrupt handler function, user still need to set the MTIMERCMP or MTIMER to reload the system tick, if vendor want to use this timer's auto clear feature, they can define __Vendor_SysTickConfig to 1, and implement SysTick_Config and SysTick_Reload functions.
- When the variable __Vendor_SysTickConfig is set to 1, then the function SysTick_Reload is not included.
- In this case, the file **<Device>.h** must contain a vendor-specific implementation of this function.
- This function only available when __SYSTIMER_PRESENT == 1 and __ECLIC_PRESENT == 1 and __Vendor_SysTickConfig == 0
- Since the MTIMERCMP value might overflow, if overflowed, MTIMER will be set to 0, and MTIMERCMP set to ticks

See

- SysTimer_SetCompareValue
- SysTimer_SetLoadValue

Parameters

- [in] ticks: Number of ticks between two interrupts.

SysTick Code Example

The code below shows the usage of the function SysTick_Config() and SysTick_Reload() with an GD32VF103 SoC.

Listing 3: gd32vf103_systick_example.c

```

1  #include "gd32vf103.h"
2
3  volatile uint32_t msTicks = 0;           /* Variable to store_
   ↳millisecond ticks */
4
5  #define CONFIG_TICKS      (SOC_TIMER_FREQ / 1000)
6  #define SysTick_Handler   eclic_mtip_handler
7
8  void SysTick_Handler(void) {             /* SysTick interrupt_
   ↳Handler. */
9      SysTimer_Reload(CONFIG_TICKS);       /* Call SysTick_Reload to_
   ↳reload timer. */
10     msTicks++;                           /* See startup file_
   ↳startup_gd32vf103.S for SysTick vector */
11 }
12
13 int main (void) {
14     uint32_t returnCode;
15
16     returnCode = SysTick_Config(CONFIG_TICKS); /* Configure SysTick to_
   ↳generate an interrupt every millisecond */
17
18     if (returnCode != 0) {                 /* Check return code for_
   ↳errors */
19         // Error Handling
20     }
21
22     while(1);
23 }

```

SysTimer Interrupt Code Example

The code below shows the usage of various NMSIS Timer Interrupt functions with an GD32VF103 device.

Listing 4: gd32vf103_timer_example1.c

```

1  #include "gd32vf103.h"
2
3  void eclic_mtip_handler(void)
4  {
5      uint64_t now = SysTimer_GetLoadValue();
6      SysTimer_SetCompareValue(now + SOC_TIMER_FREQ/100);
7  }
8
9  static uint32_t int_cnt = 0;
10 void eclic_msip_handler(void)
11 {
12     SysTimer_ClearSWIRQ();
13     int_cnt++;

```

26     ECLIC_SetLevelIRQ(IRQn, lvl);
27     ECLIC_SetPriorityIRQ(IRQn, priority);
28     ECLIC_SetVector(IRQn, (rv_csr_t) (handler));
29     ECLIC_EnableIRQ(IRQn);
30     return 0;
31 }
32
33 void setup_timer(void)
34 {
35     SysTimer_SetLoadValue(0);
36     SysTimer_SetCompareValue(SOC_TIMER_FREQ/100);
37 }
38
39 int main (void)
40 {
41     uint32_t returnCode;
42
43     eclic_global_initialize();           /* initialize ECLIC */
44
45     setup_timer();                       /* initialize timer */
46
47     returnCode = eclic_register_interrupt(SysTimer_IRQn,1,2,8,0,eclic_mtip_handler);
↳/* register system timer interrupt */
48
49     returnCode = eclic_register_interrupt(SysTimerSW_IRQn,1,2,8,0,eclic_msip_handler);
↳ /* register system timer SW interrupt */
50
51     __enable_irq();                     /* enable global
↳interrupt */
52
53     SysTimer_SetSWIRQ();                 /* trigger timer SW
↳interrupt */
54
55     if (returnCode != 0) {               /* Check return code
↳for errors */
56         // Error Handling
57     }
58
59     while(1);
60 }

```

2.5.10 Interrupts and Exceptions

Description

This section explains how to use interrupts and exceptions and access functions for the [Enhanced Core Local Interrupt Controller\(ECLIC\)](#)¹⁸.

Nuclei provides a template file `startup_device` for each supported compiler. The file must be adapted by the silicon vendor to include interrupt vectors for all device-specific interrupt handlers. Each interrupt handler is defined as a weak function to a dummy handler. These interrupt handlers can be used directly in application software without being adapted by the programmer.

Click [Interrupt](#)¹⁹ to learn more about interrupt handling in Nuclei processor core.

NMI Interrupt

[NMI interrupt](#)²⁰ entry is stored by `CSR_MNVEC`. If `CSR_MMSIC[9]` is 1 then NMI entry is the same as **Exception** which get from `CSR_MTVEC`. If `CSR_MMSIC[9]` is 1 NMI entry is reset vector.

Exception

[Exception](#)²¹ has only 1 entry address which stored by `CSR_MTVEC`. All the exceptions will jump to the same entry `exc_entry` defined in `intexc_<Device>.S`.

The table below lists the core exception code of the Nuclei N/NX processors.

Table 8: Core exception code of the Nuclei N/NX processors

Exception Code	Value	Description
<code>InsUnalign_EXCn</code>	0	Instruction address misaligned
<code>InsAccFault_EXCn</code>	1	Instruction access fault
<code>IlleIns_EXCn</code>	2	Illegal instruction
<code>Break_EXCn</code>	3	Beakpoint
<code>LdAddrUnalign_EXCn</code>	4	Load address misaligned
<code>LdFault_EXCn</code>	5	Load access fault
<code>StAddrUnalign_EXCn</code>	6	Store or AMO address misaligned
<code>StAccessFault_EXCn</code>	7	Store or AMO access fault
<code>UmodeEcall_EXCn</code>	8	Environment call from User mode
<code>MmodeEcall_EXCn</code>	11	Environment call from Machine mode
<code>NMI_EXCn</code>	0xff	NMI interrupt

Vector Table

The Vector Table defines the entry addresses of the ECLIC managed interrupts.

It is typically located at the beginning of the program memory, and you can modify `CSR_MTVT` to reallocate the base address of this vector table, but you need to take care of the base address alignment according to the number of interrupts.

¹⁸ https://doc.nucleisys.com/nuclei_spec/isa/eclic.html

¹⁹ https://doc.nucleisys.com/nuclei_spec/isa/interrupt.html

²⁰ https://doc.nucleisys.com/nuclei_spec/isa/nmi.html

²¹ https://doc.nucleisys.com/nuclei_spec/isa/exception.html

Table 9: base address alignment according to the number of interrupts

Number of Interrupt	Alignment Requirements of CSR MTVT
0 to 16	64-byte
17 to 32	128-byte
33 to 64	256-byte
65 to 128	512-byte
129 to 256	1KB
257 to 512	2KB
513 to 1024	4KB

Interrupt number 0~18 is reserved by Nuclei Core. 19~1023 could be used by Silicon Vendor Device.

Below is an example interrupt allocated table:

```

1 typedef enum IRQn {
2     /***** Nuclei N/NX Processor Core Internal Interrupt Numbers *****/
3     Reserved0_IRQn = 0,    /*!< Internal reserved
4     Reserved1_IRQn = 1,    /*!< Internal reserved
5     Reserved2_IRQn = 2,    /*!< Internal reserved
6     SysTimerSW_IRQn = 3,   /*!< System Timer SW interrupt
7     Reserved3_IRQn = 4,    /*!< Internal reserved

32  ↪ */
    } IRQn_Type;

```

ECLIC API Definitions

When macro NMSIS_ECLIC_VIRTUAL is defined, the ECLIC access functions in the table below must be implemented for virtualizing ECLIC access.

These functions should be implemented in a separate source module. The original NMSIS-Core __ECLIC_XXX functions are always available independent of NMSIS_ECLIC_VIRTUAL macro.

Table 10: ECLIC Access Functions

ECLIC ACCESS FUNCTIONS	NMSIS-CORE FUNCTIONS FOR ECLIC
<i>ECLIC_SetCfgNbBits</i> (page 291)	__ECLIC_SetCfgNbBits()
<i>ECLIC_GetCfgNbBits</i> (page 291)	__ECLIC_GetCfgNbBits()
<i>ECLIC_GetInfoVer</i> (page 291)	__ECLIC_GetInfoVer()

When NMSIS_VECTAB_VIRTUAL macro is defined, the functions in the table below must be replaced to virtualize the API access functions to the interrupt vector table.

The ECLIC vector table API should be implemented in a separate source module.

This allows, for example, alternate implementations to relocate the vector table from flash to RAM on the first vector table update.

The original NMSIS-Core functions are always available, but prefixed with `__ECLIC`.

Table 11: ECLIC Vector Access Functions

ECLIC Vector Table Access	NMSIS-CORE FUNCTIONS
<code>ECLIC_SetVector</code> (page 291)	<code>__ECLIC_SetVector()</code>
<code>ECLIC_GetVector</code> (page 291)	<code>__ECLIC_GetVector()</code>

ECLIC Function Usage

The code below shows the usage of various NMSIS ECLIC flow with an GD32VF103 device.

Listing 5: gd32vf103_interrupt_example1.c

```

1  #include "gd32vf103.h"
2
3  // Vector interrupt which could be nested
4  __INTERCEPT void eclic_button1_handler(void)
5  {
6      SAVE_IRQ_CSR_CONTEXT(); /* save mepc,
7      ↳ mcause, msubm enable interrupts */
8      GPIO_REG(GPIO_OUTPUT_VAL) |= (1 << GREEN_LED_GPIO_OFFSET); /* Green LED On_
9      ↳ */
10     GPIO_REG(GPIO_RISE_IP) = (0x1 << BUTTON_1_GPIO_OFFSET); /* Clear the_
11     ↳ GPIO Pending interrupt by writing 1. */
12     RESTORE_IRQ_CSR_CONTEXT(); /* disable_
13     ↳ interrupts, restore mepc, mcause, msubm */
14 }
15 // Non-vector interrupt
16 void eclic_button2_handler(void)
17 {
18     GPIO_REG(GPIO_OUTPUT_VAL) |= (1 << GREEN_LED_GPIO_OFFSET); /* Green LED On_
19     ↳ */
20     GPIO_REG(GPIO_RISE_IP) = (0x1 << BUTTON_2_GPIO_OFFSET); /* Clear the_
21     ↳ GPIO Pending interrupt by writing 1. */
22 }
23 void eclic_global_initialize(void)
24 {
25     ECLIC_SetMth(0);
26     ECLIC_SetCfgNlbits(3);
27 }
28 int eclic_register_interrupt(IRQn_Type IRQn, uint8_t shv, uint32_t trig_mode, uint32_t_
29 ↳ lvl, uint32_t priority, void * handler)
30 {

```

(continues on next page)

(continued from previous page)

```

29     ECLIC_SetShvIRQ(IRQn, shv);
30     ECLIC_SetTrigIRQ(IRQn, trig_mode);
31     ECLIC_SetLevelIRQ(IRQn, lvl);
32     ECLIC_SetPriorityIRQ(IRQn, priority);
33     ECLIC_SetVector(IRQn, (rv_csr_t)(handler));
34     ECLIC_EnableIRQ(IRQn);
35     return 0;
36 }
37
38 int main (void)
39 {
40     uint32_t returnCode;
41
42     eclic_global_initialize();           /* initialize ECLIC */
43
44     GPIO_init();                       /* initialize GPIO */
45
46     returnCode = eclic_register_interrupt(BTN1_IRQn, 1, 2, 1, 0, Button1_IRQHandler); /*
↳register system button1 interrupt */
47     returnCode = eclic_register_interrupt(BTN2_IRQn, 0, 2, 2, 0, Button2_IRQHandler); /*
↳register system button2 interrupt */
48
49     __enable_irq();                   /* enable global
↳interrupt */
50
51     if (returnCode != 0) {             /* Check return code
↳for errors */
52         // Error Handling
53     }
54
55     while(1);
56 }

```

SAVE_IRQ_CSR_CONTEXT ()

Save necessary CSRs into variables for vector interrupt nesting.

This macro is used to declare variables which are used for saving CSRs(MCAUSE, MEPC, MSUB), and it will read these CSR content into these variables, it need to be used in a vector-interrupt if nesting is required.

Remark

- Interrupt will be enabled after this macro is called
- It need to be used together with **RESTORE_IRQ_CSR_CONTEXT**
- Don't use variable names __mcause, __mpec, __msubm in your ISR code
- If you want to enable interrupt nesting feature for vector interrupt, you can do it like this:

```
// __INTERRUPT attribute will generates function entry and exit_
↪sequences suitable
// for use in an interrupt handler when this attribute is present
__INTERRUPT void eclic_mtip_handler(void)
{
    // Must call this to save CSRs
    SAVE_IRQ_CSR_CONTEXT();
    // !!!Interrupt is enabled here!!!
    // !!!Higher priority interrupt could nest it!!!

    // put you own interrupt handling code here

    // Must call this to restore CSRs
    RESTORE_IRQ_CSR_CONTEXT();
}
```

RESTORE_IRQ_CSR_CONTEXT()

Restore necessary CSRs from variables for vector interrupt nesting.

This macro is used restore CSRs(MCAUSE, MEPC, MSUB) from pre-defined variables in SAVE_IRQ_CSR_CONTEXT macro.

Remark

- Interrupt will be disabled after this macro is called
- It need to be used together with SAVE_IRQ_CSR_CONTEXT

Enums**enum IRQn_Type**

Definition of IRQn numbers.

The core interrupt enumeration names for IRQn values are defined in the file <Device>.h.

- Interrupt ID(IRQn) from 0 to 18 are reserved for core internal interrupts.
- Interrupt ID(IRQn) start from 19 represent device-specific external interrupts.
- The first device-specific interrupt has the IRQn value 19.

The table below describes the core interrupt names and their availability in various Nuclei Cores.

Values:

Reserved0_IRQn = 0

Internal reserved.

Reserved1_IRQn = 1

Internal reserved.

Reserved2_IRQn = 2

Internal reserved.

SysTimerSW_IRQn = 3

System Timer SW interrupt.

Reserved3_IRQn = 4

Internal reserved.

Reserved4_IRQn = 5

Internal reserved.

Reserved5_IRQn = 6

Internal reserved.

SysTimer_IRQn = 7

System Timer Interrupt.

Reserved6_IRQn = 8

Internal reserved.

Reserved7_IRQn = 9

Internal reserved.

Reserved8_IRQn = 10

Internal reserved.

Reserved9_IRQn = 11

Internal reserved.

Reserved10_IRQn = 12

Internal reserved.

Reserved11_IRQn = 13

Internal reserved.

Reserved12_IRQn = 14

Internal reserved.

Reserved13_IRQn = 15

Internal reserved.

Reserved14_IRQn = 16

Internal reserved.

Reserved15_IRQn = 17

Internal reserved.

Reserved16_IRQn = 18

Internal reserved.

FirstDeviceSpecificInterrupt_IRQn = 19

First Device Specific Interrupt.

SOC_INT_MAX

Number of total interrupts.

Functions

__STATIC_FORCEINLINE void __ECLIC_SetCfgNlbits(uint32_t nlbits)

Set nlbits value.

This function set the nlbits value of CLICCFG register.

Remark

- nlbits is used to set the width of level in the CLICINTCTL[i].

See

- ECLIC_GetCfgNlbits

Parameters

- [in] nlbits: nlbits value

__STATIC_FORCEINLINE uint32_t __ECLIC_GetCfgNlbits(void)

Get nlbits value.

This function get the nlbits value of CLICCFG register.

Return nlbits value of CLICCFG register

Remark

- nlbits is used to set the width of level in the CLICINTCTL[i].

See

- ECLIC_SetCfgNlbits

__STATIC_FORCEINLINE uint32_t __ECLIC_GetInfoVer(void)

Get the ECLIC version number.

This function gets the hardware version information from CLICINFO register.

Return hardware version number in CLICINFO register.

Remark

- This function gets hardware version information from CLICINFO register.
- Bit 20:17 for architecture version, bit 16:13 for implementation version.

See

- ECLIC_GetInfoNum

__STATIC_FORCEINLINE uint32_t __ECLIC_GetInfoCtlbits(void)

Get CLICINTCTLBITS.

This function gets CLICINTCTLBITS from CLICINFO register.

Return CLICINTCTLBITS from CLICINFO register.

Remark

- In the CLICINTCTL[i] registers, with $2 \leq \text{CLICINTCTLBITS} \leq 8$.
- The implemented bits are kept left-justified in the most-significant bits of each 8-bit CLICINTCTL[I] register, with the lower unimplemented bits treated as hardwired to 1.

See

- ECLIC_GetInfoNum

__STATIC_FORCEINLINE uint32_t __ECLIC_GetInfoNum(void)

Get number of maximum interrupt inputs supported.

This function gets number of maximum interrupt inputs supported from CLICINFO register.

Return number of maximum interrupt inputs supported from CLICINFO register.

Remark

- This function gets number of maximum interrupt inputs supported from CLICINFO register.
- The num_interrupt field specifies the actual number of maximum interrupt inputs supported in this implementation.

See

- ECLIC_GetInfoCtlbits

__STATIC_FORCEINLINE void __ECLIC_SetMth(uint8_t mth)
Set Machine Mode Interrupt Level Threshold.

This function sets machine mode interrupt level threshold.

See

- ECLIC_GetMth

Parameters

- [in] mth: Interrupt Level Threshold.

__STATIC_FORCEINLINE uint8_t __ECLIC_GetMth(void)
Get Machine Mode Interrupt Level Threshold.

This function gets machine mode interrupt level threshold.

Return Interrupt Level Threshold.

See

- ECLIC_SetMth

__STATIC_FORCEINLINE void __ECLIC_EnableIRQ(IRQn_Type IRQn)
Enable a specific interrupt.

This function enables the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.

See

- ECLIC_DisableIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE uint32_t __ECLIC_GetEnableIRQ(IRQn_Type IRQn)
Get a specific interrupt enable status.

This function returns the interrupt enable status for the specific interrupt *IRQn*.

Return

- 0 Interrupt is not enabled
- 1 Interrupt is pending

Remark

- IRQn must not be negative.

See

- ECLIC_EnableIRQ
- ECLIC_DisableIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_DisableIRQ(IRQn_Type IRQn)
Disable a specific interrupt.

This function disables the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.

See

- ECLIC_EnableIRQ

Parameters

- [in] IRQn: Number of the external interrupt to disable

__STATIC_FORCEINLINE int32_t __ECLIC_GetPendingIRQ(IRQn_Type IRQn)

Get the pending specific interrupt.

This function returns the pending status of the specific interrupt *IRQn*.

Return

- 0 Interrupt is not pending
- 1 Interrupt is pending

Remark

- IRQn must not be negative.

See

- ECLIC_SetPendingIRQ
- ECLIC_ClearPendingIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_SetPendingIRQ(IRQn_Type IRQn)

Set a specific interrupt to pending.

This function sets the pending bit for the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.

See

- ECLIC_GetPendingIRQ
- ECLIC_ClearPendingIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_ClearPendingIRQ(IRQn_Type IRQn)

Clear a specific interrupt from pending.

This function removes the pending state of the specific interrupt *IRQn*. *IRQn* cannot be a negative number.

Remark

- IRQn must not be negative.

See

- ECLIC_SetPendingIRQ
- ECLIC_GetPendingIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_SetTrigIRQ(IRQn_Type IRQn, uint32_t trig)

Set trigger mode and polarity for a specific interrupt.

This function set trigger mode and polarity of the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.

See

- ECLIC_GetTrigIRQ

Parameters

- [in] IRQn: Interrupt number
- [in] trig:
 - 00 level trigger, [ECLIC_LEVEL_TRIGGER](#) (page 84)
 - 01 positive edge trigger, [ECLIC_POSTIVE_EDGE_TRIGGER](#) (page 84)
 - 02 level trigger, [ECLIC_LEVEL_TRIGGER](#) (page 84)
 - 03 negative edge trigger, [ECLIC_NEGTIVE_EDGE_TRIGGER](#) (page 84)

__STATIC_FORCEINLINE uint32_t __ECLIC_GetTrigIRQ(IRQn_Type IRQn)

Get trigger mode and polarity for a specific interrupt.

This function get trigger mode and polarity of the specific interrupt *IRQn*.

Return

- 00 level trigger, [ECLIC_LEVEL_TRIGGER](#) (page 84)
- 01 positive edge trigger, [ECLIC_POSTIVE_EDGE_TRIGGER](#) (page 84)
- 02 level trigger, [ECLIC_LEVEL_TRIGGER](#) (page 84)
- 03 negative edge trigger, [ECLIC_NEGTIVE_EDGE_TRIGGER](#) (page 84)

Remark

- IRQn must not be negative.

See

- ECLIC_SetTrigIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_SetShvIRQ(IRQn_Type IRQn, uint32_t shv)

Set interrupt working mode for a specific interrupt.

This function set selective hardware vector or non-vector working mode of the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.

See

- ECLIC_GetShvIRQ

Parameters

- [in] IRQn: Interrupt number
- [in] shv:
 - 0 non-vector mode, *ECLIC_NON_VECTOR_INTERRUPT* (page 84)
 - 1 vector mode, *ECLIC_VECTOR_INTERRUPT* (page 84)

__STATIC_FORCEINLINE uint32_t __ECLIC_GetShvIRQ(IRQn_Type IRQn)

Get interrupt working mode for a specific interrupt.

This function get selective hardware vector or non-vector working mode of the specific interrupt *IRQn*.

Return shv

- 0 non-vector mode, *ECLIC_NON_VECTOR_INTERRUPT* (page 84)
- 1 vector mode, *ECLIC_VECTOR_INTERRUPT* (page 84)

Remark

- IRQn must not be negative.

See

- ECLIC_SetShvIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_SetCtrlIRQ(IRQn_Type IRQn, uint8_t intctrl)

Modify ECLIC Interrupt Input Control Register for a specific interrupt.

This function modify ECLIC Interrupt Input Control(CLICINTCTL[i]) register of the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.

See

- ECLIC_GetCtrlIRQ

Parameters

- [in] IRQn: Interrupt number
- [in] intctrl: Set value for CLICINTCTL[i] register

__STATIC_FORCEINLINE uint8_t __ECLIC_GetCtrlIRQ(IRQn_Type IRQn)

Get ECLIC Interrupt Input Control Register value for a specific interrupt.

This function modify ECLIC Interrupt Input Control register of the specific interrupt *IRQn*.

Return value of ECLIC Interrupt Input Control register

Remark

- IRQn must not be negative.

See

- ECLIC_SetCtrlIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_SetLevelIRQ(IRQn_Type IRQn, uint8_t lvl_abs)
Set ECLIC Interrupt level of a specific interrupt.

This function set interrupt level of the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.
- If lvl_abs to be set is larger than the max level allowed, it will be force to be max level.
- When you set level value you need use clciinfo.nbits to get the width of level. Then we could know the maximum of level. CLICINTCTLBITS is how many total bits are present in the CLICINTCTL register.

See

- ECLIC_GetLevelIRQ

Parameters

- [in] IRQn: Interrupt number
- [in] lvl_abs: Interrupt level

__STATIC_FORCEINLINE uint8_t __ECLIC_GetLevelIRQ(IRQn_Type IRQn)
Get ECLIC Interrupt level of a specific interrupt.

This function get interrupt level of the specific interrupt *IRQn*.

Return Interrupt level

Remark

- IRQn must not be negative.

See

- ECLIC_SetLevelIRQ

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __ECLIC_SetPriorityIRQ(IRQn_Type IRQn, uint8_t pri)
Get ECLIC Interrupt priority of a specific interrupt.

This function get interrupt priority of the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.
- If pri to be set is larger than the max priority allowed, it will be force to be max priority.
- Priority width is CLICINTCTLBITS minus clciinfo.nbits if clciinfo.nbits is less than CLICINTCTLBITS. Otherwise priority width is 0.

See

- ECLIC_GetPriorityIRQ

Parameters

- [in] IRQn: Interrupt number
- [in] pri: Interrupt priority

```
__STATIC_FORCEINLINE uint8_t __ECLIC_GetPriorityIRQ(IRQn_Type IRQn)
```

Get ECLIC Interrupt priority of a specific interrupt.

This function get interrupt priority of the specific interrupt *IRQn*.

Return Interrupt priority

Remark

- IRQn must not be negative.

See

- ECLIC_SetPriorityIRQ

Parameters

- [in] IRQn: Interrupt number

```
__STATIC_FORCEINLINE void __ECLIC_SetVector(IRQn_Type IRQn, rv_csr_t vector)
```

Set Interrupt Vector of a specific interrupt.

This function set interrupt handler address of the specific interrupt *IRQn*.

Remark

- IRQn must not be negative.
- You can set the CSR_CSR_MTVT to set interrupt vector table entry address.
- If your vector table is placed in readonly section, the vector for IRQn will not be modified. For this case, you need to use the correct irq handler name defined in your vector table as your irq handler function name.
- This function will only work correctly when the vector table is placed in an read-write enabled section.

See

- ECLIC_GetVector

Parameters

- [in] IRQn: Interrupt number
- [in] vector: Interrupt handler address

```
__STATIC_FORCEINLINE rv_csr_t __ECLIC_GetVector(IRQn_Type IRQn)
```

Get Interrupt Vector of a specific interrupt.

This function get interrupt handler address of the specific interrupt *IRQn*.

Return Interrupt handler address

Remark

- IRQn must not be negative.
- You can read CSR_CSR_MTVT to get interrupt vector table entry address.

See

- ECLIC_SetVector

Parameters

- [in] IRQn: Interrupt number

__STATIC_FORCEINLINE void __set_exc_entry(rv_csr_t addr)

Set Exception entry address.

This function set exception handler address to 'CSR_MTVEC'.

Remark

- This function use to set exception handler address to 'CSR_MTVEC'. Address is 4 bytes align.

See

- __get_exc_entry

Parameters

- [in] addr: Exception handler address

__STATIC_FORCEINLINE rv_csr_t __get_exc_entry(void)

Get Exception entry address.

This function get exception handler address from 'CSR_MTVEC'.

Return Exception handler address

Remark

- This function use to get exception handler address from 'CSR_MTVEC'. Address is 4 bytes align

See

- __set_exc_entry

__STATIC_FORCEINLINE void __set_nonvec_entry(rv_csr_t addr)

Set Non-vector interrupt entry address.

This function set Non-vector interrupt address.

Remark

- This function use to set non-vector interrupt entry address to 'CSR_MTVT2' if
- CSR_MTVT2 bit0 is 1. If 'CSR_MTVT2' bit0 is 0 then set address to 'CSR_MTVEC'

See

- __get_nonvec_entry

Parameters

- [in] addr: Non-vector interrupt entry address

__STATIC_FORCEINLINE rv_csr_t __get_nonvec_entry(void)

Get Non-vector interrupt entry address.

This function get Non-vector interrupt address.

Return Non-vector interrupt handler address

Remark

- This function use to get non-vector interrupt entry address from 'CSR_MTVT2' if
- CSR_MTVT2 bit0 is 1. If 'CSR_MTVT2' bit0 is 0 then get address from 'CSR_MTVEC'.

See

- __set_nonvec_entry

__STATIC_FORCEINLINE rv_csr_t __get_nmi_entry(void)

Get NMI interrupt entry from 'CSR_MNVEC'.

This function get NMI interrupt address from 'CSR_MNVEC'.

Return NMI interrupt handler address

Remark

- This function use to get NMI interrupt handler address from 'CSR_MNVEC'. If CSR_MMISC_CTL[9] = 1 'CSR_MNVEC'
- will be equal as mtvec. If CSR_MMISC_CTL[9] = 0 'CSR_MNVEC' will be equal as reset vector.
- NMI entry is defined via [CSR_MMISC_CTL](#) (page 69), writing to [CSR_MNVEC](#) (page 69) will be ignored.

2.5.11 FPU Functions

group NMSIS_Core_FPU_Functions

Functions that related to the RISC-V FPU (F and D extension).

Nuclei provided floating point unit by RISC-V F and D extension.

- F extension adds single-precision floating-point computational instructions compliant with the IEEE 754-2008 arithmetic standard, __RISCV_FLEN = 32. The F extension adds 32 floating-point registers, f0-f31, each 32 bits wide, and a floating-point control and status register fcsr, which contains the operating mode and exception status of the floating-point unit.
- D extension adds double-precision floating-point computational instructions compliant with the IEEE 754-2008 arithmetic standard. The D extension widens the 32 floating-point registers, f0-f31, to 64 bits, __RISCV_FLEN = 64

Defines

__RISCV_FLEN 64

__get_FCSR() [__RV_CSR_READ](#) (page 61)([CSR_FCSR](#) (page 63))

Get FCSR CSR Register.

__set_FCSR(val) [__RV_CSR_WRITE](#) (page 61)([CSR_FCSR](#) (page 63), (val))

Set FCSR CSR Register with val.

__get_FRM() [__RV_CSR_READ](#) (page 61)([CSR_FRM](#) (page 63))

Get FRM CSR Register.

__set_FRM(val) [__RV_CSR_WRITE](#) (page 61)([CSR_FRM](#) (page 63), (val))

Set FRM CSR Register with val.

__get_FFLAGS() [__RV_CSR_READ](#) (page 61)([CSR_FFLAGS](#) (page 63))

Get FFLAGS CSR Register.

__set_FFLAGS(val) [__RV_CSR_WRITE](#) (page 61)([CSR_FFLAGS](#) (page 63), (val))

Set FFLAGS CSR Register with val.

__enable_FPU() [__RV_CSR_SET](#) (page 61)([CSR_MSTATUS](#) (page 64), [MSTATUS_FS](#) (page 70))

Enable FPU Unit.

`__disable_FPU()` `__RV_CSR_CLEAR` (page 62)(`CSR_MSTATUS` (page 64), `MSTATUS_FS` (page 70))
Disable FPU Unit.

- We can save power by disable FPU Unit.
- When FPU Unit is disabled, any access to FPU related CSR registers and FPU instructions will cause illegal Instruction Exception.

`__RV_FLW` (freg, addr, ofs)

Load a single-precision value from memory into float point register freg using flw instruction.

The FLW instruction loads a single-precision floating point value from memory address (addr + ofs) into floating point register freg(f0-f31)

Remark

- FLW and FSW operations need to make sure the address is 4 bytes aligned, otherwise it will cause exception code 4(Load address misaligned) or 6 (Store/AMO address misaligned)
- FLW and FSW do not modify the bits being transferred; in particular, the payloads of non-canonical NaNs are preserved

Parameters

- [in] freg: The floating point register, eg. `FREG(0)` (page 76), f0
- [in] addr: The memory base address, 4 byte aligned required
- [in] ofs: a 12-bit immediate signed byte offset value, should be an const value

`__RV_FSW` (freg, addr, ofs)

Store a single-precision value from float point freg into memory using fsw instruction.

The FSW instruction stores a single-precision value from floating point register to memory

Remark

- FLW and FSW operations need to make sure the address is 4 bytes aligned, otherwise it will cause exception code 4(Load address misaligned) or 6 (Store/AMO address misaligned)
- FLW and FSW do not modify the bits being transferred; in particular, the payloads of non-canonical NaNs are preserved

Parameters

- [in] freg: The floating point register(f0-f31), eg. `FREG(0)` (page 76), f0
- [in] addr: The memory base address, 4 byte aligned required
- [in] ofs: a 12-bit immediate signed byte offset value, should be an const value

`__RV_FLD` (freg, addr, ofs)

Load a double-precision value from memory into float point register freg using fld instruction.

The FLD instruction loads a double-precision floating point value from memory address (addr + ofs) into floating point register freg(f0-f31)

Attention

- Function only available for double precision floating point unit, FLEN = 64

Remark

- FLD and FSD operations need to make sure the address is 8 bytes aligned, otherwise it will cause exception code 4(Load address misaligned) or 6 (Store/AMO address misaligned)

- FLD and FSD do not modify the bits being transferred; in particular, the payloads of non-canonical NaNs are preserved.

Parameters

- [in] *freg*: The floating point register, eg. *FREG(0)* (page 76), *f0*
- [in] *addr*: The memory base address, 8 byte aligned required
- [in] *ofs*: a 12-bit immediate signed byte offset value, should be an const value

`__RV_FSD` (*freg*, *addr*, *ofs*)

Store a double-precision value from float point *freg* into memory using *fsd* instruction.

The FSD instruction stores double-precision value from floating point register to memory

Attention

- Function only available for double precision floating point unit, *FLEN* = 64

Remark

- FLD and FSD operations need to make sure the address is 8 bytes aligned, otherwise it will cause exception code 4(Load address misaligned) or 6 (Store/AMO address misaligned)
- FLD and FSD do not modify the bits being transferred; in particular, the payloads of non-canonical NaNs are preserved.

Parameters

- [in] *freg*: The floating point register(*f0*-*f31*), eg. *FREG(0)* (page 76), *f0*
- [in] *addr*: The memory base address, 8 byte aligned required
- [in] *ofs*: a 12-bit immediate signed byte offset value, should be an const value

`__RV_FLOAD` `__RV_FLD` (page 304)

Load a float point value from memory into float point register *freg* using *flw/fld* instruction.

- For Single-Precision Floating-Point Mode(*__FPU_PRESENT* == 1, *__RISCV_FLEN* == 32): It will call `__RV_FLW` (page 304) to load a single-precision floating point value from memory to floating point register
- For Double-Precision Floating-Point Mode(*__FPU_PRESENT* == 2, *__RISCV_FLEN* == 64): It will call `__RV_FLD` (page 304) to load a double-precision floating point value from memory to floating point register

Attention Function behaviour is different for *__FPU_PRESENT* = 1 or 2, please see the real function this macro represent

`__RV_FSTORE` `__RV_FSD` (page 305)

Store a float value from float point *freg* into memory using *fsw/fsd* instruction.

- For Single-Precision Floating-Point Mode(*__FPU_PRESENT* == 1, *__RISCV_FLEN* == 32): It will call `__RV_FSW` (page 304) to store floating point register into memory
- For Double-Precision Floating-Point Mode(*__FPU_PRESENT* == 2, *__RISCV_FLEN* == 64): It will call `__RV_FSD` (page 305) to store floating point register into memory

Attention Function behaviour is different for *__FPU_PRESENT* = 1 or 2, please see the real function this macro represent

SAVE_FPU_CONTEXT ()

Save FPU context into variables for interrupt nesting.

This macro is used to declare variables which are used for saving FPU context, and it will store the necessary fpu registers into these variables, it needs to be used in an interrupt when the fpu registers are used.

Remark

- It needs to be used together with [RESTORE_FPU_CONTEXT](#) (page 306)
- Don't use variable names `__fpu_context` in your ISR code
- If your ISR code will use fpu registers, and this interrupt is nested. Then you can do it like this:

```
void eclic_mtip_handler(void)
{
    // !!!Interrupt is enabled here!!!
    // !!!Higher priority interrupt could nest it!!!

    // Necessary only when you need to use fpu registers
    // in this isr handler functions
    SAVE_FPU_CONTEXT();

    // put your own interrupt handling code here

    // pair of SAVE_FPU_CONTEXT()
    RESTORE_FPU_CONTEXT();
}
```

RESTORE_FPU_CONTEXT ()

Restore necessary fpu registers from variables for interrupt nesting.

This macro is used to restore necessary fpu registers from pre-defined variables in [SAVE_FPU_CONTEXT](#) (page 306) macro.

Remark

- It needs to be used together with [SAVE_FPU_CONTEXT](#) (page 306)

Typedefs

```
typedef uint64_t rv_fpu_t
```

Type of FPU register, depends on the FLEN defined in RISC-V.

2.5.12 PMP Functions

Click [Nuclei PMP Unit](#)²² to learn about Core PMP Unit in Nuclei ISA Spec.

```
__STATIC_INLINE uint8_t __get_PMPxCFG(uint32_t idx)
__STATIC_INLINE void __set_PMPxCFG(uint32_t idx, uint8_t pmpcfg)
__STATIC_INLINE rv_csr_t __get_PMPCFGx(uint32_t idx)
__STATIC_INLINE void __set_PMPCFGx(uint32_t idx, rv_csr_t pmpcfg)
__STATIC_INLINE rv_csr_t __get_PMPADDRx(uint32_t idx)
```

²² https://doc.nucleisys.com/nuclei_spec/isa/pmp.html

```
__STATIC_INLINE void __set_PMPADDRx(uint32_t idx, rv_csr_t pmpaddr)
```

group NMSIS_Core_PMP_Functions

Functions that related to the RISC-V Physical Memory Protection.

Optional physical memory protection (PMP) unit provides per-hart machine-mode control registers to allow physical memory access privileges (read, write, execute) to be specified for each physical memory region.

The PMP can supports region access control settings as small as four bytes.

Functions

```
__STATIC_INLINE uint8_t __get_PMPxCFG(uint32_t idx)
```

Get 8bit PMPxCFG Register by PMP entry index.

Return the content of the PMPxCFG Register.

Return PMPxCFG Register value

Parameters

- [in] idx: PMP region index(0-15)

```
__STATIC_INLINE void __set_PMPxCFG(uint32_t idx, uint8_t pmpxcfg)
```

Set 8bit PMPxCFG by pmp entry index.

Set the given pmpxcfg value to the PMPxCFG Register.

Parameters

- [in] idx: PMPx region index(0-15)
- [in] pmpxcfg: PMPxCFG register value to set

```
__STATIC_INLINE rv_csr_t __get_PMPCFGx(uint32_t idx)
```

Get PMPCFGx Register by index.

Return the content of the PMPCFGx Register.

Return PMPCFGx Register value

Remark

- For RV64, only idx = 0 and idx = 2 is allowed. pmpcfg0 and pmpcfg2 hold the configurations for the 16 PMP entries, pmpcfg1 and pmpcfg3 are illegal
- For RV32, pmpcfg0–pmpcfg3, hold the configurations pmp0cfg–pmp15cfg for the 16 PMP entries

Parameters

- [in] idx: PMPCFG CSR index(0-3)

```
__STATIC_INLINE void __set_PMPCFGx(uint32_t idx, rv_csr_t pmpcfg)
```

Set PMPCFGx by index.

Write the given value to the PMPCFGx Register.

Remark

- For RV64, only idx = 0 and idx = 2 is allowed. pmpcfg0 and pmpcfg2 hold the configurations for the 16 PMP entries, pmpcfg1 and pmpcfg3 are illegal
- For RV32, pmpcfg0–pmpcfg3, hold the configurations pmp0cfg–pmp15cfg for the 16 PMP entries

Parameters

- [in] idx: PMPCFG CSR index(0-3)
- [in] pmpcfg: PMPCFGx Register value to set

__STATIC_INLINE rv_csr_t __get_PMPADDRx(uint32_t idx)

Get PMPADDRx Register by index.

Return the content of the PMPADDRx Register.

Return PMPADDRx Register value

Parameters

- [in] idx: PMP region index(0-15)

__STATIC_INLINE void __set_PMPADDRx(uint32_t idx, rv_csr_t pmpaddr)

Set PMPADDRx by index.

Write the given value to the PMPADDRx Register.

Parameters

- [in] idx: PMP region index(0-15)
- [in] pmpaddr: PMPADDRx Register value to set

2.5.13 Cache Functions

General

enum NMSIS_Core_Cache::CCM_OP_FINFO_Type

Values:

CCM_OP_SUCCESS = 0x0

CCM_OP_EXCEED_ERR = 0x1

CCM_OP_PERM_CHECK_ERR = 0x2

CCM_OP_REFILL_BUS_ERR = 0x3

CCM_OP_ECC_ERR = 0x4

enum NMSIS_Core_Cache::CCM_CMD_Type

Values:

CCM_DC_INVALID = 0x0

CCM_DC_WB = 0x1

CCM_DC_WBINVAL = 0x2

CCM_DC_LOCK = 0x3

CCM_DC_UNLOCK = 0x4

CCM_DC_WBINVAL_ALL = 0x6

CCM_DC_WB_ALL = 0x7

CCM_DC_INVALID_ALL = 0x17

CCM_IC_INVALID = 0x8

CCM_IC_LOCK = 0xb

```

CCM_IC_UNLOCK = 0xc
CCM_IC_INVALID_ALL = 0xd
__STATIC_FORCEINLINE void EnableSUCCM(void)
__STATIC_FORCEINLINE void DisableSUCCM(void)
__STATIC_FORCEINLINE void FlushPipeCCM(void)
CCM_SUEN_SUEN_Pos 0U
CCM_SUEN_SUEN_Msk (1UL << CCM_SUEN_SUEN_Pos)

```

group NMSIS_Core_Cache

Functions that configure Instruction and Data Cache.

Nuclei provide Cache Control and Maintenance (CCM) for software to control and maintain the internal L1 I/D Cache of the RISC-V Core, software can manage the cache flexibly to meet the actual application scenarios.

The CCM operations have 3 types: by single address, by all and flush pipeline. The CCM operations are done via CSR registers, M/S/U mode has its own CSR registers to do CCM operations. By default, CCM operations are not allowed in S/U mode, you can execute EnableSUCCM in M-Mode to enable it.

- API names started with M<operations>, such as MInvalICacheLine must be called in M-Mode only.
- API names started with S<operations>, such as SInvalICacheLine should be called in S-Mode.
- API names started with U<operations>, such as UInvalICacheLine should be called in U-Mode.

Defines

```

CCM_SUEN_SUEN_Pos 0U
    CSR CCM_SUEN: SUEN bit Position.
CCM_SUEN_SUEN_Msk (1UL << CCM_SUEN_SUEN_Pos)
    CSR CCM_SUEN: SUEN Mask.

```

Enums

enum CCM_OP_FINFO_Type

Cache CCM Operation Fail Info.

Values:

```

CCM_OP_SUCCESS = 0x0
    Lock Succeed.

CCM_OP_EXCEED_ERR = 0x1
    Exceed the the number of lockable ways(N-Way I/D-Cache, lockable is N-1)

CCM_OP_PERM_CHECK_ERR = 0x2
    PMP/sPMP/Page-Table X(I-Cache)/R(D-Cache) permission check failed, or belong to Device/Non-
    Cacheable address range.

CCM_OP_REFILL_BUS_ERR = 0x3
    Refill has Bus Error.

CCM_OP_ECC_ERR = 0x4
    ECC Error.

```

enum CCM_CMD_Type

Cache CCM Command Types.

Values:

CCM_DC_INVALID = 0x0

Unlock and invalidate D-Cache line specified by CSR CCM_XBEGINADDR.

CCM_DC_WB = 0x1

Flush the specific D-Cache line specified by CSR CCM_XBEGINADDR.

CCM_DC_WBINVAL = 0x2

Unlock, flush and invalidate the specific D-Cache line specified by CSR CCM_XBEGINADDR.

CCM_DC_LOCK = 0x3

Lock the specific D-Cache line specified by CSR CCM_XBEGINADDR.

CCM_DC_UNLOCK = 0x4

Unlock the specific D-Cache line specified by CSR CCM_XBEGINADDR.

CCM_DC_WBINVAL_ALL = 0x6

Unlock and flush and invalidate all the valid and dirty D-Cache lines.

CCM_DC_WB_ALL = 0x7

Flush all the valid and dirty D-Cache lines.

CCM_DC_INVALID_ALL = 0x17

Unlock and invalidate all the D-Cache lines.

CCM_IC_INVALID = 0x8

Unlock and invalidate I-Cache line specified by CSR CCM_XBEGINADDR.

CCM_IC_LOCK = 0xb

Lock the specific I-Cache line specified by CSR CCM_XBEGINADDR.

CCM_IC_UNLOCK = 0xc

Unlock the specific I-Cache line specified by CSR CCM_XBEGINADDR.

CCM_IC_INVALID_ALL = 0xd

Unlock and invalidate all the I-Cache lines.

Functions

__STATIC_FORCEINLINE void EnableSUCCM(void)

Enable CCM operation in Supervisor/User Mode.

This function enable CCM operation in Supervisor/User Mode. If enabled, CCM operations in supervisor/user mode will be allowed.

Remark

- This function can be called in M-Mode only.

See

- DisableSUCCM

__STATIC_FORCEINLINE void DisableSUCCM(void)

Disable CCM operation in Supervisor/User Mode.

This function disable CCM operation in Supervisor/User Mode. If not enabled, CCM operations in supervisor/user mode will trigger a *illegal intruction* exception.

Remark

- This function can be called in M-Mode only.

See

- EnableSUCCM

__STATIC_FORCEINLINE void FlushPipeCCM(void)

Flush pipeline after CCM operation.

This function is used to flush pipeline after CCM operations on Cache, it will ensure latest instructions or data can be seen by pipeline.

Remark

- This function can be called in M/S/U-Mode only.

I-Cache Functions

```
__STATIC_FORCEINLINE void EnableICache(void)

__STATIC_FORCEINLINE void MInvalICache(void)
__STATIC_FORCEINLINE void SInvalICache(void)
__STATIC_FORCEINLINE void UInvalICache(void)
```

group **NMSIS_Core_ICache**

Functions that configure Instruction Cache.

Functions

__STATIC_FORCEINLINE void EnableICache(void)

Enable ICache.

This function enable I-Cache

Remark

- This function can be called in M-Mode only.
- This [CSR_MCACHE_CTL](#) (page 69) register control I Cache enable.

See

- DisableICache

__STATIC_FORCEINLINE void DisableICache(void)

Disable ICache.

This function Disable I-Cache

Remark

- This function can be called in M-Mode only.
- This [CSR_MCACHE_CTL](#) (page 69) register control I Cache enable.

See

- EnableICache

__STATIC_FORCEINLINE void MInvalidICacheLine(unsigned long addr)

Invalidate one I-Cache line specified by address in M-Mode.

This function unlock and invalidate one I-Cache line specified by the address. Command CCM_IC_INVALID is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void MInvalidICacheLines(unsigned long addr, unsigned long cnt)

Invalidate several I-Cache lines specified by address in M-Mode.

This function unlock and invalidate several I-Cache lines specified by the address and line count. Command CCM_IC_INVALID is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be invalidated
- [in] cnt: count of cache lines to be invalidated

__STATIC_FORCEINLINE void SInvalidICacheLine(unsigned long addr)

Invalidate one I-Cache line specified by address in S-Mode.

This function unlock and invalidate one I-Cache line specified by the address. Command CCM_IC_INVALID is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void SInvalidCacheLines(unsigned long addr, unsigned long cnt)
Invalidate several I-Cache lines specified by address in S-Mode.

This function unlock and invalidate several I-Cache lines specified by the address and line count. Command CCM_IC_INVALID is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be invalidated
- [in] cnt: count of cache lines to be invalidated

__STATIC_FORCEINLINE void UInvalidCacheLine(unsigned long addr)
Invalidate one I-Cache line specified by address in U-Mode.

This function unlock and invalidate one I-Cache line specified by the address. Command CCM_IC_INVALID is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void UInvalidCacheLines(unsigned long addr, unsigned long cnt)
Invalidate several I-Cache lines specified by address in U-Mode.

This function unlock and invalidate several I-Cache lines specified by the address and line count. Command CCM_IC_INVALID is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be invalidated
- [in] cnt: count of cache lines to be invalidated

__STATIC_FORCEINLINE unsigned long MLockICacheLine(unsigned long addr)
Lock one I-Cache line specified by address in M-Mode.

This function lock one I-Cache line specified by the address. Command CCM_IC_LOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked

__STATIC_FORCEINLINE unsigned long MLockICacheLines(unsigned long addr, unsigned long cnt)
Lock several I-Cache lines specified by address in M-Mode.

This function lock several I-Cache lines specified by the address and line count. Command CCM_IC_LOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked
- [in] cnt: count of cache lines to be locked

__STATIC_FORCEINLINE unsigned long SLockICacheLine(unsigned long addr)

Lock one I-Cache line specified by address in S-Mode.

This function lock one I-Cache line specified by the address. Command CCM_IC_LOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked

__STATIC_FORCEINLINE unsigned long SLockICacheLines(unsigned long addr, unsigned long cnt)

Lock several I-Cache lines specified by address in S-Mode.

This function lock several I-Cache lines specified by the address and line count. Command CCM_IC_LOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked
- [in] cnt: count of cache lines to be locked

__STATIC_FORCEINLINE unsigned long ULockICacheLine(unsigned long addr)

Lock one I-Cache line specified by address in U-Mode.

This function lock one I-Cache line specified by the address. Command CCM_IC_LOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked

__STATIC_FORCEINLINE unsigned long ULockICacheLines(unsigned long addr, unsigned long cnt)

Lock several I-Cache lines specified by address in U-Mode.

This function lock several I-Cache lines specified by the address and line count. Command CCM_IC_LOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked
- [in] cnt: count of cache lines to be locked

__STATIC_FORCEINLINE void MUnlockICacheLine(unsigned long addr)

Unlock one I-Cache line specified by address in M-Mode.

This function unlock one I-Cache line specified by the address. Command CCM_IC_UNLOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be unlocked

__STATIC_FORCEINLINE void MUnlockICacheLines(unsigned long addr, unsigned long cnt)

Unlock several I-Cache lines specified by address in M-Mode.

This function unlock several I-Cache lines specified by the address and line count. Command CCM_IC_UNLOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be unlocked
- [in] cnt: count of cache lines to be unlocked

__STATIC_FORCEINLINE void SUnlockICacheLine(unsigned long addr)

Unlock one I-Cache line specified by address in S-Mode.

This function unlock one I-Cache line specified by the address. Command CCM_IC_UNLOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be unlocked

__STATIC_FORCEINLINE void SUnlockICacheLines(unsigned long addr, unsigned long cnt)

Unlock several I-Cache lines specified by address in S-Mode.

This function unlock several I-Cache lines specified by the address and line count. Command CCM_IC_UNLOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be unlocked
- [in] cnt: count of cache lines to be unlocked

__STATIC_FORCEINLINE void UUnlockICacheLine(unsigned long addr)

Unlock one I-Cache line specified by address in U-Mode.

This function unlock one I-Cache line specified by the address. Command CCM_IC_UNLOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be unlocked

__STATIC_FORCEINLINE void UUnlockICacheLines(unsigned long addr, unsigned long cnt)

Unlock several I-Cache lines specified by address in U-Mode.

This function unlock several I-Cache lines specified by the address and line count. Command CCM_IC_UNLOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be unlocked
- [in] cnt: count of cache lines to be unlocked

__STATIC_FORCEINLINE void MInvalidCache(void)

Invalidate all I-Cache lines in M-Mode.

This function invalidate all I-Cache lines. Command CCM_IC_INVAL_ALL is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.**Parameters**

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void SInvalidCache(void)

Invalidate all I-Cache lines in S-Mode.

This function invalidate all I-Cache lines. Command CCM_IC_INVAL_ALL is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.**Parameters**

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void UInvalidCache(void)

Invalidate all I-Cache lines in U-Mode.

This function invalidate all I-Cache lines. Command CCM_IC_INVAL_ALL is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.**Parameters**

- [in] addr: start address to be invalidated

```

group **NMSIS_Core_DCache**

Functions that configure Data Cache.

Functions

```
__STATIC_FORCEINLINE void EnabledDCache(void)
```

Enable DCache.

This function enable D-Cache

Remark

- This function can be called in M-Mode only.
- This [CSR_MCACHE_CTL](#) (page 69) register control D Cache enable.

See

- DisabledDCache

__STATIC_FORCEINLINE void DisabledDCache(void)

Disable DCache.

This function Disable D-Cache

Remark

- This function can be called in M-Mode only.
- This [CSR_MCACHE_CTL](#) (page 69) register control D Cache enable.

See

- EnableDCache

__STATIC_FORCEINLINE void MInvalidDCacheLine(unsigned long addr)

Invalidate one D-Cache line specified by address in M-Mode.

This function unlock and invalidate one D-Cache line specified by the address. Command CCM_DC_INVALID is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void MInvalidDCacheLines(unsigned long addr, unsigned long cnt)

Invalidate several D-Cache lines specified by address in M-Mode.

This function unlock and invalidate several D-Cache lines specified by the address and line count. Command CCM_DC_INVALID is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be invalidated
- [in] cnt: count of cache lines to be invalidated

__STATIC_FORCEINLINE void SInvalidDCacheLine(unsigned long addr)

Invalidate one D-Cache line specified by address in S-Mode.

This function unlock and invalidate one D-Cache line specified by the address. Command CCM_DC_INVALID is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void SInvalidDCacheLines(unsigned long addr, unsigned long cnt)

Invalidate several D-Cache lines specified by address in S-Mode.

This function unlock and invalidate several D-Cache lines specified by the address and line count. Command CCM_DC_INVALID is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be invalidated
- [in] cnt: count of cache lines to be invalidated

__STATIC_FORCEINLINE void UInvalDCacheLine(unsigned long addr)

Invalidate one D-Cache line specified by address in U-Mode.

This function unlock and invalidate one D-Cache line specified by the address. Command CCM_DC_INVALID is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void UInvalDCacheLines(unsigned long addr, unsigned long cnt)

Invalidate several D-Cache lines specified by address in U-Mode.

This function unlock and invalidate several D-Cache lines specified by the address and line count. Command CCM_DC_INVALID is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be invalidated
- [in] cnt: count of cache lines to be invalidated

__STATIC_FORCEINLINE void MFlushDCacheLine(unsigned long addr)

Flush one D-Cache line specified by address in M-Mode.

This function flush one D-Cache line specified by the address. Command CCM_DC_WB is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be flushed

__STATIC_FORCEINLINE void MFlushDCacheLines(unsigned long addr, unsigned long cnt)

Flush several D-Cache lines specified by address in M-Mode.

This function flush several D-Cache lines specified by the address and line count. Command CCM_DC_WB is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be flushed
- [in] cnt: count of cache lines to be flushed

__STATIC_FORCEINLINE void SFlushDCacheLine(unsigned long addr)

Flush one D-Cache line specified by address in S-Mode.

This function flush one D-Cache line specified by the address. Command CCM_DC_WB is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be flushed

__STATIC_FORCEINLINE void SFlushDCacheLines(unsigned long addr, unsigned long cnt)
Flush several D-Cache lines specified by address in S-Mode.

This function flush several D-Cache lines specified by the address and line count. Command CCM_DC_WB is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be flushed
- [in] cnt: count of cache lines to be flushed

__STATIC_FORCEINLINE void UFlushDCacheLine(unsigned long addr)
Flush one D-Cache line specified by address in U-Mode.

This function flush one D-Cache line specified by the address. Command CCM_DC_WB is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be flushed

__STATIC_FORCEINLINE void UFlushDCacheLines(unsigned long addr, unsigned long cnt)
Flush several D-Cache lines specified by address in U-Mode.

This function flush several D-Cache lines specified by the address and line count. Command CCM_DC_WB is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be flushed
- [in] cnt: count of cache lines to be flushed

__STATIC_FORCEINLINE void MFlushInvalDCacheLine(unsigned long addr)
Flush and invalidate one D-Cache line specified by address in M-Mode.

This function flush and invalidate one D-Cache line specified by the address. Command CCM_DC_WBINVAL is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be flushed and invalidated

__STATIC_FORCEINLINE void MFlushInvalDCacheLines(unsigned long addr, unsigned long cnt)
Flush and invalidate several D-Cache lines specified by address in M-Mode.

This function flush and invalidate several D-Cache lines specified by the address and line count. Command CCM_DC_WBINVAL is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be flushed and invalidated
- [in] cnt: count of cache lines to be flushed and invalidated

__STATIC_FORCEINLINE void SFlushInvalDCacheLine(unsigned long addr)

Flush and invalidate one D-Cache line specified by address in S-Mode.

This function flush and invalidate one D-Cache line specified by the address. Command CCM_DC_WBINVAL is written to CSR *CSR_CCM_SCOMMAND* (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be flushed and invalidated

__STATIC_FORCEINLINE void SFlushInvalDCacheLines(unsigned long addr, unsigned long cnt)

Flush and invalidate several D-Cache lines specified by address in S-Mode.

This function flush and invalidate several D-Cache lines specified by the address and line count. Command CCM_DC_WBINVAL is written to CSR *CSR_CCM_SCOMMAND* (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be flushed and invalidated
- [in] cnt: count of cache lines to be flushed and invalidated

__STATIC_FORCEINLINE void UFlushInvalDCacheLine(unsigned long addr)

Flush and invalidate one D-Cache line specified by address in U-Mode.

This function flush and invalidate one D-Cache line specified by the address. Command CCM_DC_WBINVAL is written to CSR *CSR_CCM_UCOMMAND* (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be flushed and invalidated

__STATIC_FORCEINLINE void UFlushInvalDCacheLines(unsigned long addr, unsigned long cnt)

Flush and invalidate several D-Cache lines specified by address in U-Mode.

This function flush and invalidate several D-Cache lines specified by the address and line count. Command CCM_DC_WBINVAL is written to CSR *CSR_CCM_UCOMMAND* (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be flushed and invalidated
- [in] cnt: count of cache lines to be flushed and invalidated

__STATIC_FORCEINLINE unsigned long MLockDCacheLine(unsigned long addr)

Lock one D-Cache line specified by address in M-Mode.

This function lock one D-Cache line specified by the address. Command CCM_DC_LOCK is written to CSR *CSR_CCM_MCOMMAND* (page 70).

Remark This function must be executed in M-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked

__STATIC_FORCEINLINE unsigned long MLockDCacheLines(unsigned long addr, unsigned long cnt)
Lock several D-Cache lines specified by address in M-Mode.

This function lock several D-Cache lines specified by the address and line count. Command CCM_DC_LOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked
- [in] cnt: count of cache lines to be locked

__STATIC_FORCEINLINE unsigned long SLockDCacheLine(unsigned long addr)
Lock one D-Cache line specified by address in S-Mode.

This function lock one D-Cache line specified by the address. Command CCM_DC_LOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked

__STATIC_FORCEINLINE unsigned long SLockDCacheLines(unsigned long addr, unsigned long cnt)
Lock several D-Cache lines specified by address in S-Mode.

This function lock several D-Cache lines specified by the address and line count. Command CCM_DC_LOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked
- [in] cnt: count of cache lines to be locked

__STATIC_FORCEINLINE unsigned long ULockDCacheLine(unsigned long addr)
Lock one D-Cache line specified by address in U-Mode.

This function lock one D-Cache line specified by the address. Command CCM_DC_LOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked

__STATIC_FORCEINLINE unsigned long ULockDCacheLines(unsigned long addr, unsigned long cnt)
Lock several D-Cache lines specified by address in U-Mode.

This function lock several D-Cache lines specified by the address and line count. Command CCM_DC_LOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Return result of CCM lock operation, see enum CCM_OP_FINFO

Parameters

- [in] addr: start address to be locked
- [in] cnt: count of cache lines to be locked

__STATIC_FORCEINLINE void MUnlockDCacheLine(unsigned long addr)

Unlock one D-Cache line specified by address in M-Mode.

This function unlock one D-Cache line specified by the address. Command CCM_DC_UNLOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be unlocked

__STATIC_FORCEINLINE void MUnlockDCacheLines(unsigned long addr, unsigned long cnt)

Unlock several D-Cache lines specified by address in M-Mode.

This function unlock several D-Cache lines specified by the address and line count. Command CCM_DC_UNLOCK is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be unlocked
- [in] cnt: count of cache lines to be unlocked

__STATIC_FORCEINLINE void SUnlockDCacheLine(unsigned long addr)

Unlock one D-Cache line specified by address in S-Mode.

This function unlock one D-Cache line specified by the address. Command CCM_DC_UNLOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be unlocked

__STATIC_FORCEINLINE void SUnlockDCacheLines(unsigned long addr, unsigned long cnt)

Unlock several D-Cache lines specified by address in S-Mode.

This function unlock several D-Cache lines specified by the address and line count. Command CCM_DC_UNLOCK is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be unlocked
- [in] cnt: count of cache lines to be unlocked

__STATIC_FORCEINLINE void UUnlockDCacheLine(unsigned long addr)

Unlock one D-Cache line specified by address in U-Mode.

This function unlock one D-Cache line specified by the address. Command CCM_DC_UNLOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be unlocked

__STATIC_FORCEINLINE void UUnlockDCacheLines(unsigned long addr, unsigned long cnt)

Unlock several D-Cache lines specified by address in U-Mode.

This function unlock several D-Cache lines specified by the address and line count. Command CCM_DC_UNLOCK is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be unlocked
- [in] cnt: count of cache lines to be unlocked

__STATIC_FORCEINLINE void MInvalidDCache(void)

Invalidate all D-Cache lines in M-Mode.

This function invalidate all D-Cache lines. Command CCM_DC_INVALID_ALL is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void SInvalidDCache(void)

Invalidate all D-Cache lines in S-Mode.

This function invalidate all D-Cache lines. Command CCM_DC_INVALID_ALL is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void UInvalidDCache(void)

Invalidate all D-Cache lines in U-Mode.

This function invalidate all D-Cache lines. In U-Mode, this operation will be automatically translated to flush and invalidate operations by hardware. Command CCM_DC_INVALID_ALL is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be invalidated

__STATIC_FORCEINLINE void MFlushDCache(void)

Flush all D-Cache lines in M-Mode.

This function flush all D-Cache lines. Command CCM_DC_WB_ALL is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be flushed

__STATIC_FORCEINLINE void SFlushDCache(void)

Flush all D-Cache lines in S-Mode.

This function flush all D-Cache lines. Command CCM_DC_WB_ALL is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be flushed

__STATIC_FORCEINLINE void UFlushDCache(void)

Flush all D-Cache lines in U-Mode.

This function flush all D-Cache lines. Command CCM_DC_WB_ALL is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be flushed

__STATIC_FORCEINLINE void MFlushInvalDCache(void)

Flush and invalidate all D-Cache lines in M-Mode.

This function flush and invalidate all D-Cache lines. Command CCM_DC_WBINVAL_ALL is written to CSR [CSR_CCM_MCOMMAND](#) (page 70).

Remark This function must be executed in M-Mode only.

Parameters

- [in] addr: start address to be flushed and locked

__STATIC_FORCEINLINE void SFlushInvalDCache(void)

Flush and invalidate all D-Cache lines in S-Mode.

This function flush and invalidate all D-Cache lines. Command CCM_DC_WBINVAL_ALL is written to CSR [CSR_CCM_SCOMMAND](#) (page 70).

Remark This function must be executed in M/S-Mode only.

Parameters

- [in] addr: start address to be flushed and locked

__STATIC_FORCEINLINE void UFlushInvalDCache(void)

Flush and invalidate all D-Cache lines in U-Mode.

This function flush and invalidate all D-Cache lines. Command CCM_DC_WBINVAL_ALL is written to CSR [CSR_CCM_UCOMMAND](#) (page 70).

Remark This function must be executed in M/S/U-Mode only.

Parameters

- [in] addr: start address to be flushed and locked

2.5.14 System Device Configuration

group NMSIS_Core_SystemConfig

Functions for system init, clock setup and interrupt/exception/nmi functions available in system_<device>.c.

Nuclei provides a template file **system_Device.c** that must be adapted by the silicon vendor to match their actual device. As a **minimum requirement**, this file must provide:

- A device-specific system configuration function, *SystemInit* (page 326).
- A global variable that contains the system frequency, *SystemCoreClock* (page 327).
- A global eclic configuration initialization, *ECLIC_Init* (page 329).
- Global c library *_init* (page 326) and *_fini* (page 327) functions called right before calling main function.
- Vendor customized interrupt, exception and nmi handling code, see *Interrupt and Exception and NMI Handling* (page 327)

The file configures the device and, typically, initializes the oscillator (PLL) that is part of the microcontroller device. This file might export other functions or variables that provide a more flexible configuration of the microcontroller system.

And this file also provided common interrupt, exception and NMI exception handling framework template, Silicon vendor can customize these template code as they want.

Note Please pay special attention to the static variable `SystemCoreClock`. This variable might be used throughout the whole system initialization and runtime to calculate frequency/time related values. Thus one must assure that the variable always reflects the actual system clock speed.

Attention Be aware that a value stored to `SystemCoreClock` during low level initialization (i.e. *SystemInit()* (page 326)) might get overwritten by C library startup code and/or .bss section initialization. Thus its highly recommended to call *SystemCoreClockUpdate* (page 326) at the beginning of the user `main()` routine.

Functions

void **SystemCoreClockUpdate** (void)

Function to update the variable *SystemCoreClock* (page 327).

Updates the variable *SystemCoreClock* (page 327) and must be called whenever the core clock is changed during program execution. The function evaluates the clock register settings and calculates the current core clock.

void **SystemInit** (void)

Function to Initialize the system.

Initializes the microcontroller system. Typically, this function configures the oscillator (PLL) that is part of the microcontroller device. For systems with a variable clock speed, it updates the variable *SystemCoreClock* (page 327). `SystemInit` is called from the file **startup**.

void **_premain_init** (void)

early init function before main

This function is executed right before main function. For RISC-V gnu toolchain, `_init` function might not be called by `__libc_init_array` function, so we defined a new function to do initialization

void **_postmain_fini** (int *status*)

finish function after main

This function is executed right after main function. For RISC-V gnu toolchain, `_fini` function might not be called by `__libc_fini_array` function, so we defined a new function to do initialization

Parameters

- [in] `status`: status code return from main

void **_init** (void)

_init function called in __libc_init_array()

This __libc_init_array() function is called during startup code, user need to implement this function, otherwise when link it will error init.c:(.text.__libc_init_array+0x26): undefined reference to '_init'

Note Please use [_premain_init](#) (page 326) function now

void **_fini** (void)

_fini function called in __libc_fini_array()

This __libc_fini_array() function is called when exit main. user need to implement this function, otherwise when link it will error fini.c:(.text.__libc_fini_array+0x28): undefined reference to '_fini'

Note Please use [_postmain_fini](#) (page 326) function now

Variables

uint32_t **SystemCoreClock** = SYSTEM_CLOCK

Variable to hold the system core clock value.

Holds the system core clock, which is the system clock frequency supplied to the SysTick timer and the processor core clock. This variable can be used by debuggers to query the frequency of the debug timer or to configure the trace clock speed.

Attention Compilers must be configured to avoid removing this variable in case the application program is not using it. Debugging systems require the variable to be physically present in memory so that it can be examined to configure the debugger.

Interrupt Exception NMI Handling

group **NMSIS_Core_IntExcNMI_Handling**

Functions for interrupt, exception and nmi handle available in system_<device>.c.

Nuclei provide a template for interrupt, exception and NMI handling. Silicon Vendor could adapt according to their requirement. Silicon vendor could implement interface for different exception code and replace current implementation.

Defines

MAX_SYSTEM_EXCEPTION_NUM 12

Max exception handler number, don't include the NMI(0xFFFF) one.

Typedefs

typedef void (***EXC_HANDLER**) (unsigned long mcause, unsigned long sp)

Exception Handler Function Typedef.

Note This typedef is only used internal in this system_<Device>.c file. It is used to do type conversion for registered exception handler before calling it.

Functions

static void `system_default_exception_handler` (unsigned long *mcause*, unsigned long *sp*)
System Default Exception Handler.

This function provided a default exception and NMI handling code for all exception ids. By default, It will just print some information for debug, Vendor can customize it according to its requirements.

static void `Exception_Init` (void)
Initialize all the default core exception handlers.

The core exception handler for each exception id will be initialized to *system_default_exception_handler* (page 328).

Note Called in *_init* (page 326) function, used to initialize default exception handlers for all exception IDs

void **`Exception_DumpFrame`** (unsigned long *sp*)
Dump Exception Frame.

This function provided feature to dump exception frame stored in stack.

void **`Exception_Register_EXC`** (uint32_t *EXCn*, unsigned long *exc_handler*)
Register an exception handler for exception code EXCn.

- For *EXCn* < *MAX_SYSTEM_EXCEPTION_NUM* (page 327), it will be registered into *SystemExceptionHandlers[EXCn-1]*.
- For *EXCn* == *NMI_EXCn*, it will be registered into *SystemExceptionHandlers[MAX_SYSTEM_EXCEPTION_NUM]*.

Parameters

- *EXCn*: See *EXCn_Type*
- *exc_handler*: The exception handler for this exception code EXCn

unsigned long **`Exception_Get_EXC`** (uint32_t *EXCn*)
Get current exception handler for exception code EXCn.

- For *EXCn* < *MAX_SYSTEM_EXCEPTION_NUM* (page 327), it will return *SystemExceptionHandlers[EXCn-1]*.
- For *EXCn* == *NMI_EXCn*, it will return *SystemExceptionHandlers[MAX_SYSTEM_EXCEPTION_NUM]*.

Return Current exception handler for exception code EXCn, if not found, return 0.

Parameters

- *EXCn*: See *EXCn_Type*

uint32_t **`core_exception_handler`** (unsigned long *mcause*, unsigned long *sp*)
Common NMI and Exception handler entry.

This function provided a command entry for NMI and exception. Silicon Vendor could modify this template implementation according to requirement.

Remark

- RISCv provided common entry for all types of exception. This is proposed code template for exception entry function, Silicon Vendor could modify the implementation.

- For the `core_exception_handler` template, we provided exception register function `Exception_Register_EXCn` which can help developer to register your exception handler for specific exception number.

void **ECLIC_Init** (void)

Initialize Global ECLIC Config.

ECLIC needs be initialized after boot up, Vendor could also change the initialization configuration.

int32_t **ECLIC_Register_IRQ** (IRQn_Type *IRQn*, uint8_t *shv*, ECLIC_TRIGGER_Type *trig_mode*,
uint8_t *lvl*, uint8_t *priority*, void **handler*)

Initialize a specific IRQ and register the handler.

This function set vector mode, trigger mode and polarity, interrupt level and priority, assign handler for specific IRQn.

Return -1 means invalid input parameter. 0 means successful.

Remark

- This function use to configure specific eclic interrupt and register its interrupt handler and enable its interrupt.
- If the vector table is placed in read-only section(FLASHXIP mode), handler could not be installed

Parameters

- [in] *IRQn*: NMI interrupt handler address
- [in] *shv*: *ECLIC_NON_VECTOR_INTERRUPT* (page 84) means non-vector mode, and *ECLIC_VECTOR_INTERRUPT* (page 84) is vector mode
- [in] *trig_mode*: see *ECLIC_TRIGGER_Type* (page 84)
- [in] *lvl*: interrupt level
- [in] *priority*: interrupt priority
- [in] *handler*: interrupt handler, if NULL, handler will not be installed

Variables

unsigned long **SystemExceptionHandler**[MAX_SYSTEM_EXCEPTION_NUM + 1]

Store the exception handlers for each exception ID.

Note

- This SystemExceptionHandler are used to store all the handlers for all the exception codes Nuclei N/NX core provided.
- Exception code 0 - 11, totally 12 exceptions are mapped to SystemExceptionHandler[0:11]
- Exception for NMI is also re-routed to exception handling(exception code 0xFFFF) in startup code configuration, the handler itself is mapped to SystemExceptionHandler[MAX_SYSTEM_EXCEPTION_NUM]

2.5.15 ARM Compatible Functions

group **NMSIS_Core_ARMCompatible_Functions**

A few functions that compatible with ARM CMSIS-Core.

Here we provided a few functions that compatible with ARM CMSIS-Core, mostly used in the DSP and NN library.

Defines

__ISB () __RWMB()
Instruction Synchronization Barrier, compatible with ARM.

__DSB () __RWMB()
Data Synchronization Barrier, compatible with ARM.

__DMB () __RWMB()
Data Memory Barrier, compatible with ARM.

__LDRBT (ptr) __LB((ptr))
LDRT Unprivileged (8 bit), ARM Compatible.

__LDRHT (ptr) __LH((ptr))
LDRT Unprivileged (16 bit), ARM Compatible.

__LDRT (ptr) __LW((ptr))
LDRT Unprivileged (32 bit), ARM Compatible.

__STRBT (val, ptr) __SB((ptr), (val))
STRT Unprivileged (8 bit), ARM Compatible.

__STRHT (val, ptr) __SH((ptr), (val))
STRT Unprivileged (16 bit), ARM Compatible.

__STRT (val, ptr) __SW((ptr), (val))
STRT Unprivileged (32 bit), ARM Compatible.

__SSAT (val, sat) __RV_SCLIP32((val), (sat-1))
Signed Saturate.
Saturates a signed value.

Return Saturated value

Parameters

- [in] value: Value to be saturated
- [in] sat: Bit position to saturate to (1..32)

__USAT (val, sat) __RV_UCLIP32((val), (sat))
Unsigned Saturate.
Saturates an unsigned value.

Return Saturated value

Parameters

- [in] value: Value to be saturated
- [in] sat: Bit position to saturate to (0..31)

__RBIT (value) __RV_BITREVI((value), 31)
Reverse bit order of value.
Reverses the bit order of the given value.

Return Reversed value

Parameters

- [in] value: Value to reverse

__CLZ (data) **__RV_CLZ32**(data)

Count leading zeros.

Counts the number of leading zeros of a data value.

Return number of leading zeros in value

Parameters

- [in] data: Value to count the leading zeros

Functions

__STATIC_FORCEINLINE uint32_t __REV(uint32_t value)

Reverse byte order (32 bit)

Reverses the byte order in unsigned integer value. For example, 0x12345678 becomes 0x78563412.

Return Reversed value

Parameters

- [in] value: Value to reverse

__STATIC_FORCEINLINE uint32_t __REV16(uint32_t value)

Reverse byte order (16 bit)

Reverses the byte order within each halfword of a word. For example, 0x12345678 becomes 0x34127856.

Return Reversed value

Parameters

- [in] value: Value to reverse

__STATIC_FORCEINLINE int16_t __REVSH(int16_t value)

Reverse byte order (16 bit)

Reverses the byte order in a 16-bit value and returns the signed 16-bit result. For example, 0x0080 becomes 0x8000.

Return Reversed value

Parameters

- [in] value: Value to reverse

__STATIC_FORCEINLINE uint32_t __ROR(uint32_t op1, uint32_t op2)

Rotate Right in unsigned value (32 bit)

Rotate Right (immediate) provides the value of the contents of a register rotated by a variable number of bits.

Return Rotated value

Parameters

- [in] op1: Value to rotate
- [in] op2: Number of Bits to rotate(0-31)

3.1 Overview

3.1.1 Introduction

This user manual describes the NMSIS DSP software library, a suite of common signal processing functions for use on Nuclei N/NX Class Processors based devices.

The library is divided into a number of functions each covering a specific category:

- Basic math functions
- Fast math functions
- Complex math functions
- Filters
- Matrix functions
- Transform functions
- Motor control functions
- Statistical functions
- Support functions
- Interpolation functions

The library has separate functions for operating on 8-bit integers, 16-bit integers, 32-bit integer and 32-bit floating-point values.

3.1.2 Using the Library

The library functions are declared in the public file `riscv_math.h` which is placed in the *NMSIS/DSP/Include* folder.

Simply include this file and link the appropriate library in the application and begin calling the library functions.

The Library supports single public header file `riscv_math.h` for Nuclei N/NX Class Processors cores with little endian. Same header file will be used for floating point unit(FPU) variants.

3.1.3 Examples

The library ships with *a number of examples* (page 508) which demonstrate how to use the library functions.

3.1.4 Toolchain Support

The library has been developed and tested with RISC-V GCC Toolchain.

The library is being tested in GCC toolchain and updates on this activity will be made available shortly.

3.1.5 Building the Library

The library installer contains a **Makefile** to rebuild libraries on Nuclei RISC-V GCC toolchain in the **NMSIS/** folder.

The libraries can be built by running `make gen_dsp_lib`, it will build and install DSP library into **Library/DSP/GCC** folder.

3.1.6 Preprocessor Macros

Each library project has different preprocessor macros.

RISCV_MATH_MATRIX_CHECK: Define macro `RISCV_MATH_MATRIX_CHECK` for checking on the input and output sizes of matrices

RISCV_MATH_ROUNDING: Define macro `RISCV_MATH_ROUNDING` for rounding on support functions

RISCV_MATH_LOOPUNROLL: Define macro `RISCV_MATH_LOOPUNROLL` to enable manual loop unrolling in DSP functions

3.2 Using NMSIS-DSP

Here we will describe how to run the `nmsis dsp` examples in Nuclei Spike.

3.2.1 Preparation

- Nuclei Modified Spike - `xl_spike`
- Nuclei SDK modified for `xl_spike` branch `dev_xlspike`
- Nuclei RISC-V GNU Toolchain
- CMake `>= 3.5`

3.2.2 Tool Setup

1. Export **PATH** correctly for `xl_spike` and `riscv-nuclei-elf-gcc`

```
export PATH=/path/to/xl_spike/bin:/path/to/riscv-nuclei-elf-gcc/bin/:$PATH
```

3.2.3 Build NMSIS DSP Library

1. Download or clone NMSIS source code into **NMSIS** directory.
2. `cd` to `NMSIS/NMSIS/` directory
3. Build NMSIS DSP library using `make gen_dsp_lib`

4. Strip debug informations using `make strip_dsp_lib` to make the generated library smaller
5. The dsp library will be generated into `./Library/DSP/GCC` folder
6. The dsp libraries will be look like this:

```
$ ll Library/DSP/GCC/
total 28604
-rw-r--r-- 1 hqfang nucleisys 1847080 Jul 14 14:51 libnmsis_dsp_rv32imac.a
-rw-r--r-- 1 hqfang nucleisys 2515912 Jul 14 14:51 libnmsis_dsp_rv32imacp.a
-rw-r--r-- 1 hqfang nucleisys 1786008 Jul 14 14:51 libnmsis_dsp_rv32imafc.a
-rw-r--r-- 1 hqfang nucleisys 2377420 Jul 14 14:51 libnmsis_dsp_rv32imafcp.a
-rw-r--r-- 1 hqfang nucleisys 1785500 Jul 14 14:51 libnmsis_dsp_rv32imafdc.a
-rw-r--r-- 1 hqfang nucleisys 2367840 Jul 14 14:51 libnmsis_dsp_rv32imafdc.a
-rw-r--r-- 1 hqfang nucleisys 2374468 Jul 14 14:51 libnmsis_dsp_rv64imac.a
-rw-r--r-- 1 hqfang nucleisys 3369340 Jul 14 14:51 libnmsis_dsp_rv64imacp.a
-rw-r--r-- 1 hqfang nucleisys 2276836 Jul 14 14:51 libnmsis_dsp_rv64imafc.a
-rw-r--r-- 1 hqfang nucleisys 3151172 Jul 14 14:51 libnmsis_dsp_rv64imafcp.a
-rw-r--r-- 1 hqfang nucleisys 2275828 Jul 14 14:51 libnmsis_dsp_rv64imafdc.a
-rw-r--r-- 1 hqfang nucleisys 3140188 Jul 14 14:51 libnmsis_dsp_rv64imafdc.a
```

7. library name with extra `p` is build with RISC-V DSP enabled.

- `libnmsis_dsp_rv32imac.a`: Build for **RISCV_ARCH=rv32imac** without DSP enabled.
- `libnmsis_dsp_rv32imacp.a`: Build for **RISCV_ARCH=rv32imac** with DSP enabled.

Note:

- You can also directly build both DSP and NN library using `make gen`
 - You can strip the generated DSP and NN library using `make strip`
-

3.2.4 How to run

1. Set environment variables `NUCLEI_SDK_ROOT` and `NUCLEI_SDK_NMSIS`, and set Nuclei SDK SoC to *xl-spike*

```
export NUCLEI_SDK_ROOT=/path/to/nuclei_sdk
export NUCLEI_SDK_NMSIS=/path/to/NMSIS/NMSIS
export SOC=xlspike
```

2. Let us take `./riscv_class_marks_example/` for example
3. `cd ./riscv_class_marks_example/`
4. Run with RISC-V DSP enabled NMSIS-DSP library for CORE n307

```
# Clean project
make DSP_ENABLE=ON CORE=n307 clean
# Build project
make DSP_ENABLE=ON CORE=n307 all
# Run application using xl_spike
make DSP_ENABLE=ON CORE=n307 run
```

5. Run with RISC-V DSP disabled NMSIS-DSP library for CORE n307

```
make DSP_ENABLE=OFF CORE=n307 clean
make DSP_ENABLE=OFF CORE=n307 all
make DSP_ENABLE=OFF CORE=n307 run
```

Note:

- You can easily run this example in your hardware, if you have enough memory to run it, just modify the SOC to the one your are using in step 1.
-

3.3 NMSIS DSP API

If you want to access doxygen generated NMSIS DSP API, please click [NMSIS DSP API Doxygen Documentation](#).

3.3.1 Basic Math Functions

Vector Absolute Value

void **riscv_abs_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

void **riscv_abs_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_abs_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)

void **riscv_abs_q7** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)

group **BasicAbs**

Computes the absolute value of a vector on an element-by-element basis.

The functions support in-place computation allowing the source and destination pointers to reference the same memory buffer. There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

void **riscv_abs_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

Floating-point vector absolute value.

Return none

Parameters

- [in] pSrc: points to the input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_abs_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)

Q15 vector absolute value.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q15 value -1 (0x8000) will be saturated to the maximum allowable positive value 0x7FFF.

Parameters

- [in] *pSrc*: points to the input vector
- [out] *pDst*: points to the output vector
- [in] *blockSize*: number of samples in each vector

void **riscv_abs_q31** (**const** q31_t **pSrc*, q31_t **pDst*, uint32_t *blockSize*)
Q31 vector absolute value.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q31 value -1 (0x80000000) will be saturated to the maximum allowable positive value 0x7FFFFFFF.

Parameters

- [in] *pSrc*: points to the input vector
- [out] *pDst*: points to the output vector
- [in] *blockSize*: number of samples in each vector

void **riscv_abs_q7** (**const** q7_t **pSrc*, q7_t **pDst*, uint32_t *blockSize*)
Q7 vector absolute value.

Return none

Conditions for optimum performance Input and output buffers should be aligned by 32-bit

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q7 value -1 (0x80) will be saturated to the maximum allowable positive value 0x7F.

Parameters

- [in] *pSrc*: points to the input vector
- [out] *pDst*: points to the output vector
- [in] *blockSize*: number of samples in each vector

Vector Addition

void **riscv_add_f32** (**const** float32_t **pSrcA*, **const** float32_t **pSrcB*, float32_t **pDst*, uint32_t *blockSize*)

void **riscv_add_q15** (**const** q15_t **pSrcA*, **const** q15_t **pSrcB*, q15_t **pDst*, uint32_t *blockSize*)

void **riscv_add_q31** (**const** q31_t **pSrcA*, **const** q31_t **pSrcB*, q31_t **pDst*, uint32_t *blockSize*)

void **riscv_add_q7** (**const** q7_t **pSrcA*, **const** q7_t **pSrcB*, q7_t **pDst*, uint32_t *blockSize*)

group **BasicAdd**

Element-by-element addition of two vectors.

There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

void **riscv_add_f32** (**const** float32_t *pSrcA, **const** float32_t *pSrcB, float32_t *pDst, uint32_t blockSize)
Floating-point vector addition.

Return none

Parameters

- [in] pSrcA: points to first input vector
- [in] pSrcB: points to second input vector
- [out] pDst: points to output vector
- [in] blockSize: number of samples in each vector

void **riscv_add_q15** (**const** q15_t *pSrcA, **const** q15_t *pSrcB, q15_t *pDst, uint32_t blockSize)
Q15 vector addition.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_add_q31** (**const** q31_t *pSrcA, **const** q31_t *pSrcB, q31_t *pDst, uint32_t blockSize)
Q31 vector addition.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_add_q7** (**const** q7_t *pSrcA, **const** q7_t *pSrcB, q7_t *pDst, uint32_t blockSize)
Q7 vector addition.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] are saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

Vector Dot Product

```
void riscv_dot_prod_f32 (const float32_t *pSrcA, const float32_t *pSrcB, uint32_t blockSize,
                        float32_t *result)
```

```
void riscv_dot_prod_q15 (const q15_t *pSrcA, const q15_t *pSrcB, uint32_t blockSize, q63_t *re-
                        sult)
```

```
void riscv_dot_prod_q31 (const q31_t *pSrcA, const q31_t *pSrcB, uint32_t blockSize, q63_t *re-
                        sult)
```

```
void riscv_dot_prod_q7 (const q7_t *pSrcA, const q7_t *pSrcB, uint32_t blockSize, q31_t *result)
```

group BasicDotProd

Computes the dot product of two vectors. The vectors are multiplied element-by-element and then summed.

There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

```
void riscv_dot_prod_f32 (const float32_t *pSrcA, const float32_t *pSrcB, uint32_t blockSize,
                        float32_t *result)
```

Dot product of floating-point vectors.

Return none

Parameters

- [in] pSrcA: points to the first input vector.
- [in] pSrcB: points to the second input vector.
- [in] blockSize: number of samples in each vector.
- [out] result: output result returned here.

```
void riscv_dot_prod_q15 (const q15_t *pSrcA, const q15_t *pSrcB, uint32_t blockSize, q63_t
                        *result)
```

Dot product of Q15 vectors.

Return none

Scaling and Overflow Behavior The intermediate multiplications are in $1.15 \times 1.15 = 2.30$ format and these results are added to a 64-bit accumulator in 34.30 format. Nonsaturating additions are used and given that there are 33 guard bits in the accumulator there is no risk of overflow. The return result is in 34.30 format.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [in] blockSize: number of samples in each vector

- [out] result: output result returned here

void **riscv_dot_prod_q31** (const q31_t *pSrcA, const q31_t *pSrcB, uint32_t blockSize, q63_t *result)

Dot product of Q31 vectors.

Return none

Scaling and Overflow Behavior The intermediate multiplications are in $1.31 \times 1.31 = 2.62$ format and these are truncated to 2.48 format by discarding the lower 14 bits. The 2.48 result is then added without saturation to a 64-bit accumulator in 16.48 format. There are 15 guard bits in the accumulator and there is no risk of overflow as long as the length of the vectors is less than 2^{16} elements. The return result is in 16.48 format.

Parameters

- [in] pSrcA: points to the first input vector.
- [in] pSrcB: points to the second input vector.
- [in] blockSize: number of samples in each vector.
- [out] result: output result returned here.

void **riscv_dot_prod_q7** (const q7_t *pSrcA, const q7_t *pSrcB, uint32_t blockSize, q31_t *result)

Dot product of Q7 vectors.

Return none

Scaling and Overflow Behavior The intermediate multiplications are in $1.7 \times 1.7 = 2.14$ format and these results are added to an accumulator in 18.14 format. Nonsaturating additions are used and there is no danger of wrap around as long as the vectors are less than 2^{18} elements long. The return result is in 18.14 format.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [in] blockSize: number of samples in each vector
- [out] result: output result returned here

Vector Multiplication

void **riscv_mult_f32** (const float32_t *pSrcA, const float32_t *pSrcB, float32_t *pDst, uint32_t blockSize)

void **riscv_mult_q15** (const q15_t *pSrcA, const q15_t *pSrcB, q15_t *pDst, uint32_t blockSize)

void **riscv_mult_q31** (const q31_t *pSrcA, const q31_t *pSrcB, q31_t *pDst, uint32_t blockSize)

void **riscv_mult_q7** (const q7_t *pSrcA, const q7_t *pSrcB, q7_t *pDst, uint32_t blockSize)

group **BasicMult**

Element-by-element multiplication of two vectors.

There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

void **riscv_mult_f32** (const float32_t *pSrcA, const float32_t *pSrcB, float32_t *pDst, uint32_t blockSize)
Floating-point vector multiplication.

Return none

Parameters

- [in] pSrcA: points to the first input vector.
- [in] pSrcB: points to the second input vector.
- [out] pDst: points to the output vector.
- [in] blockSize: number of samples in each vector.

void **riscv_mult_q15** (const q15_t *pSrcA, const q15_t *pSrcB, q15_t *pDst, uint32_t blockSize)
Q15 vector multiplication.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] pSrcA: points to first input vector
- [in] pSrcB: points to second input vector
- [out] pDst: points to output vector
- [in] blockSize: number of samples in each vector

void **riscv_mult_q31** (const q31_t *pSrcA, const q31_t *pSrcB, q31_t *pDst, uint32_t blockSize)
Q31 vector multiplication.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrcA: points to the first input vector.
- [in] pSrcB: points to the second input vector.
- [out] pDst: points to the output vector.
- [in] blockSize: number of samples in each vector.

void **riscv_mult_q7** (const q7_t *pSrcA, const q7_t *pSrcB, q7_t *pDst, uint32_t blockSize)
Q7 vector multiplication.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] are saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

Vector Negate

void **riscv_negate_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

void **riscv_negate_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_negate_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)

void **riscv_negate_q7** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)

group BasicNegate

Negates the elements of a vector.

The functions support in-place computation allowing the source and destination pointers to reference the same memory buffer. There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

void **riscv_negate_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

Negates the elements of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to input vector.
- [out] pDst: points to output vector.
- [in] blockSize: number of samples in each vector.

void **riscv_negate_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)

Negates the elements of a Q15 vector.

Return none

Conditions for optimum performance Input and output buffers should be aligned by 32-bit

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q15 value -1 (0x8000) is saturated to the maximum allowable positive value 0x7FFF.

Parameters

- [in] pSrc: points to the input vector.
- [out] pDst: points to the output vector.
- [in] blockSize: number of samples in each vector.

void **riscv_negate_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)

Negates the elements of a Q31 vector.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q31 value -1 (0x80000000) is saturated to the maximum allowable positive value 0x7FFFFFFF.

Parameters

- [in] pSrc: points to the input vector.
- [out] pDst: points to the output vector.
- [in] blockSize: number of samples in each vector.

void **riscv_negate_q7** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)
Negates the elements of a Q7 vector.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q7 value -1 (0x80) is saturated to the maximum allowable positive value 0x7F.

Parameters

- [in] pSrc: points to the input vector.
- [out] pDst: points to the output vector.
- [in] blockSize: number of samples in each vector.

Vector Offset

void **riscv_offset_f32** (const float32_t *pSrc, float32_t offset, float32_t *pDst, uint32_t blockSize)

void **riscv_offset_q15** (const q15_t *pSrc, q15_t offset, q15_t *pDst, uint32_t blockSize)

void **riscv_offset_q31** (const q31_t *pSrc, q31_t offset, q31_t *pDst, uint32_t blockSize)

void **riscv_offset_q7** (const q7_t *pSrc, q7_t offset, q7_t *pDst, uint32_t blockSize)

group **BasicOffset**

Adds a constant offset to each element of a vector.

The functions support in-place computation allowing the source and destination pointers to reference the same memory buffer. There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

void **riscv_offset_f32** (const float32_t *pSrc, float32_t offset, float32_t *pDst, uint32_t blockSize)

Adds a constant offset to a floating-point vector.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] offset: is the offset to be added
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_offset_q15** (const q15_t *pSrc, q15_t offset, q15_t *pDst, uint32_t blockSize)

Adds a constant offset to a Q15 vector.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] pSrc: points to the input vector
- [in] offset: is the offset to be added
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_offset_q31** (const q31_t *pSrc, q31_t offset, q31_t *pDst, uint32_t blockSize)

Adds a constant offset to a Q31 vector.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrc: points to the input vector
- [in] offset: is the offset to be added
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_offset_q7** (const q7_t *pSrc, q7_t offset, q7_t *pDst, uint32_t blockSize)

Adds a constant offset to a Q7 vector.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] are saturated.

Parameters

- [in] pSrc: points to the input vector
- [in] offset: is the offset to be added
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

Vector Scale

void **riscv_scale_f32** (const float32_t *pSrc, float32_t scale, float32_t *pDst, uint32_t blockSize)

void **riscv_scale_q15** (const q15_t *pSrc, q15_t scaleFract, int8_t shift, q15_t *pDst, uint32_t blockSize)

void **riscv_scale_q31** (const q31_t *pSrc, q31_t scaleFract, int8_t shift, q31_t *pDst, uint32_t blockSize)

void **riscv_scale_q7** (const q7_t *pSrc, q7_t scaleFract, int8_t shift, q7_t *pDst, uint32_t blockSize)

group BasicScale

Multiply a vector by a scalar value. For floating-point data, the algorithm used is:

In the fixed-point Q7, Q15, and Q31 functions, `scale` is represented by a fractional multiplication `scaleFract` and an arithmetic shift `shift`. The shift allows the gain of the scaling operation to exceed 1.0. The algorithm used with fixed-point data is:

The overall scale factor applied to the fixed-point data is

The functions support in-place computation allowing the source and destination pointers to reference the same memory buffer.

Functions

void **riscv_scale_f32** (const float32_t *pSrc, float32_t scale, float32_t *pDst, uint32_t blockSize)

Multiplies a floating-point vector by a scalar.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] scale: scale factor to be applied
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_scale_q15** (const q15_t *pSrc, q15_t scaleFract, int8_t shift, q15_t *pDst, uint32_t
blockSize)

Multiplies a Q15 vector by a scalar.

Return none

Scaling and Overflow Behavior The input data *pSrc and scaleFract are in 1.15 format. These are multiplied to yield a 2.30 intermediate result and this is shifted with saturation to 1.15 format.

Parameters

- [in] pSrc: points to the input vector
- [in] scaleFract: fractional portion of the scale value
- [in] shift: number of bits to shift the result by
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_scale_q31** (const q31_t *pSrc, q31_t scaleFract, int8_t shift, q31_t *pDst, uint32_t
blockSize)

Multiplies a Q31 vector by a scalar.

Return none

Scaling and Overflow Behavior The input data *pSrc and scaleFract are in 1.31 format. These are multiplied to yield a 2.62 intermediate result and this is shifted with saturation to 1.31 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `scaleFract`: fractional portion of the scale value
- [in] `shift`: number of bits to shift the result by
- [out] `pDst`: points to the output vector
- [in] `blockSize`: number of samples in each vector

void **riscv_scale_q7** (**const** q7_t **pSrc*, q7_t *scaleFract*, int8_t *shift*, q7_t **pDst*, uint32_t *blockSize*)

Multiplies a Q7 vector by a scalar.

Return none

Scaling and Overflow Behavior The input data `*pSrc` and `scaleFract` are in 1.7 format. These are multiplied to yield a 2.14 intermediate result and this is shifted with saturation to 1.7 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `scaleFract`: fractional portion of the scale value
- [in] `shift`: number of bits to shift the result by
- [out] `pDst`: points to the output vector
- [in] `blockSize`: number of samples in each vector

Vector Shift

void **riscv_shift_q15** (**const** q15_t **pSrc*, int8_t *shiftBits*, q15_t **pDst*, uint32_t *blockSize*)

void **riscv_shift_q31** (**const** q31_t **pSrc*, int8_t *shiftBits*, q31_t **pDst*, uint32_t *blockSize*)

void **riscv_shift_q7** (**const** q7_t **pSrc*, int8_t *shiftBits*, q7_t **pDst*, uint32_t *blockSize*)

group **BasicShift**

Shifts the elements of a fixed-point vector by a specified number of bits. There are separate functions for Q7, Q15, and Q31 data types. The underlying algorithm used is:

If `shift` is positive then the elements of the vector are shifted to the left. If `shift` is negative then the elements of the vector are shifted to the right.

The functions support in-place computation allowing the source and destination pointers to reference the same memory buffer.

Functions

void **riscv_shift_q15** (**const** q15_t **pSrc*, int8_t *shiftBits*, q15_t **pDst*, uint32_t *blockSize*)

Shifts the elements of a Q15 vector a specified number of bits.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] `pSrc`: points to the input vector

- [in] `shiftBits`: number of bits to shift. A positive value shifts left; a negative value shifts right.
- [out] `pDst`: points to the output vector
- [in] `blockSize`: number of samples in each vector

void **riscv_shift_q31** (**const** q31_t **pSrc*, int8_t *shiftBits*, q31_t **pDst*, uint32_t *blockSize*)
Shifts the elements of a Q31 vector a specified number of bits.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `shiftBits`: number of bits to shift. A positive value shifts left; a negative value shifts right.
- [out] `pDst`: points to the output vector
- [in] `blockSize`: number of samples in the vector

void **riscv_shift_q7** (**const** q7_t **pSrc*, int8_t *shiftBits*, q7_t **pDst*, uint32_t *blockSize*)
Shifts the elements of a Q7 vector a specified number of bits.

Return none

Conditions for optimum performance Input and output buffers should be aligned by 32-bit

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] are saturated.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `shiftBits`: number of bits to shift. A positive value shifts left; a negative value shifts right.
- [out] `pDst`: points to the output vector
- [in] `blockSize`: number of samples in each vector

Vector Subtraction

void **riscv_sub_f32** (**const** float32_t **pSrcA*, **const** float32_t **pSrcB*, float32_t **pDst*, uint32_t *blockSize*)

void **riscv_sub_q15** (**const** q15_t **pSrcA*, **const** q15_t **pSrcB*, q15_t **pDst*, uint32_t *blockSize*)

void **riscv_sub_q31** (**const** q31_t **pSrcA*, **const** q31_t **pSrcB*, q31_t **pDst*, uint32_t *blockSize*)

void **riscv_sub_q7** (**const** q7_t **pSrcA*, **const** q7_t **pSrcB*, q7_t **pDst*, uint32_t *blockSize*)

group **BasicSub**

Element-by-element subtraction of two vectors.

There are separate functions for floating-point, Q7, Q15, and Q31 data types.

Functions

void **riscv_sub_f32** (**const** float32_t *pSrcA, **const** float32_t *pSrcB, float32_t *pDst, uint32_t blockSize)
Floating-point vector subtraction.

Return none

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_sub_q15** (**const** q15_t *pSrcA, **const** q15_t *pSrcB, q15_t *pDst, uint32_t blockSize)
Q15 vector subtraction.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_sub_q31** (**const** q31_t *pSrcA, **const** q31_t *pSrcB, q31_t *pDst, uint32_t blockSize)
Q31 vector subtraction.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

void **riscv_sub_q7** (**const** q7_t *pSrcA, **const** q7_t *pSrcB, q7_t *pDst, uint32_t blockSize)
Q7 vector subtraction.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] will be saturated.

Parameters

- [in] pSrcA: points to the first input vector
- [in] pSrcB: points to the second input vector
- [out] pDst: points to the output vector
- [in] blockSize: number of samples in each vector

group **groupMath**

3.3.2 Fast Math Functions

Square Root

```
__STATIC_FORCEINLINE riscv_status riscv_sqrt_f32(float32_t in, float32_t * pOut)
riscv_status riscv_sqrt_q31(q31_t in, q31_t *pOut)
riscv_status riscv_sqrt_q15(q15_t in, q15_t *pOut)
void riscv_vsqr_t_f32(float32_t *pIn, float32_t *pOut, uint16_t len)
void riscv_vsqr_t_q31(q31_t *pIn, q31_t *pOut, uint16_t len)
void riscv_vsqr_t_q15(q15_t *pIn, q15_t *pOut, uint16_t len)
```

group **SQRT**

Computes the square root of a number. There are separate functions for Q15, Q31, and floating-point data types. The square root function is computed using the Newton-Raphson algorithm. This is an iterative algorithm of the form: where x_1 is the current estimate, x_0 is the previous estimate, and $f'(x_0)$ is the derivative of $f()$ evaluated at x_0 . For the square root function, the algorithm reduces to:

Functions

```
__STATIC_FORCEINLINE riscv_status riscv_sqrt_f32(float32_t in, float32_t * pOut)
Floating-point square root function.
```

Return execution status

- RISC_V_MATH_SUCCESS : input value is positive
- RISC_V_MATH_ARGUMENT_ERROR : input value is negative; *pOut is set to 0

Parameters

- [in] in: input value
- [out] pOut: square root of input value

```
riscv_status riscv_sqrt_q31(q31_t in, q31_t *pOut)
Q31 square root function.
```

Return execution status

- RISC_V_MATH_SUCCESS : input value is positive
- RISC_V_MATH_ARGUMENT_ERROR : input value is negative; *pOut is set to 0

Parameters

- [in] in: input value. The range of the input value is $[-1, 1]$ or 0x00000000 to 0x7FFFFFFF

- [out] pOut: points to square root of input value

riscv_status **riscv_sqrt_q15** (q15_t in, q15_t *pOut)
Q15 square root function.

Return execution status

- RISC_V_MATH_SUCCESS : input value is positive
- RISC_V_MATH_ARGUMENT_ERROR : input value is negative; *pOut is set to 0

Parameters

- [in] in: input value. The range of the input value is [0 +1) or 0x0000 to 0x7FFF
- [out] pOut: points to square root of input value

void **riscv_vsqr_t_f32** (float32_t *pIn, float32_t *pOut, uint16_t len)
Vector Floating-point square root function.

Return The function returns RISC_V_MATH_SUCCESS if input value is positive value or RISC_V_MATH_ARGUMENT_ERROR if in is negative value and returns zero output for negative values.

Parameters

- [in] pIn: input vector.
- [out] pOut: vector of square roots of input elements.
- [in] len: length of input vector.

void **riscv_vsqr_t_q31** (q31_t *pIn, q31_t *pOut, uint16_t len)
void **riscv_vsqr_t_q15** (q15_t *pIn, q15_t *pOut, uint16_t len)

Cosine

float32_t **riscv_cos_f32** (float32_t x)

q31_t **riscv_cos_q31** (q31_t x)

q15_t **riscv_cos_q15** (q15_t x)

group cos

Computes the trigonometric cosine function using a combination of table lookup and linear interpolation. There are separate functions for Q15, Q31, and floating-point data types. The input to the floating-point version is in radians while the fixed-point Q15 and Q31 have a scaled input with the range [0 +0.9999] mapping to [0 2*pi). The fixed-point range is chosen so that a value of 2*pi wraps around to 0.

The implementation is based on table lookup using 512 values together with linear interpolation. The steps used are:

1. Calculation of the nearest integer table index
2. Compute the fractional portion (fract) of the table index.
3. The final result equals (1.0f-fract)*a + fract*b;

where

end of sin group

Functions

`float32_t riscv_cos_f32 (float32_t x)`

Fast approximation to the trigonometric cosine function for floating-point data.

Return $\cos(x)$.

Return $\cos(x)$

Parameters

- [in] x : input value in radians.

Parameters

- [in] x : input value in radians

`q31_t riscv_cos_q31 (q31_t x)`

Fast approximation to the trigonometric cosine function for Q31 data.

The Q31 input value is in the range $[0 +0.9999]$ and is mapped to a radian value in the range $[0 \ 2\pi]$.

Return $\cos(x)$.

Return $\cos(x)$

Parameters

- [in] x : Scaled input value in radians.

Parameters

- [in] x : Scaled input value in radians

`q15_t riscv_cos_q15 (q15_t x)`

Fast approximation to the trigonometric cosine function for Q15 data.

The Q15 input value is in the range $[0 +0.9999]$ and is mapped to a radian value in the range $[0 \ 2\pi]$.

Return $\cos(x)$.

Return $\cos(x)$

Parameters

- [in] x : Scaled input value in radians.

Parameters

- [in] x : Scaled input value in radians

Sine

`float32_t riscv_sin_f32 (float32_t x)`

`q31_t riscv_sin_q31 (q31_t x)`

`q15_t riscv_sin_q15 (q15_t x)`

group **sin**

Computes the trigonometric sine function using a combination of table lookup and linear interpolation. There are separate functions for Q15, Q31, and floating-point data types. The input to the floating-point version is in radians while the fixed-point Q15 and Q31 have a scaled input with the range $[0 +0.9999]$ mapping to $[0 \ 2\pi]$. The fixed-point range is chosen so that a value of 2π wraps around to 0.

The implementation is based on table lookup using 512 values together with linear interpolation. The steps used are:

1. Calculation of the nearest integer table index
2. Compute the fractional portion (fract) of the table index.
3. The final result equals $(1.0f - \text{fract}) * a + \text{fract} * b$;

where

Functions

`float32_t riscv_sin_f32 (float32_t x)`

Fast approximation to the trigonometric sine function for floating-point data.

Return $\sin(x)$.

Return $\sin(x)$

Parameters

- `[in]` `x`: input value in radians.

Parameters

- `[in]` `x`: input value in radians.

`q31_t riscv_sin_q31 (q31_t x)`

Fast approximation to the trigonometric sine function for Q31 data.

The Q31 input value is in the range $[0 +0.9999]$ and is mapped to a radian value in the range $[0 \ 2\pi]$.

Return $\sin(x)$.

Return $\sin(x)$

Parameters

- `[in]` `x`: Scaled input value in radians.

Parameters

- `[in]` `x`: Scaled input value in radians

`q15_t riscv_sin_q15 (q15_t x)`

Fast approximation to the trigonometric sine function for Q15 data.

The Q15 input value is in the range $[0 +0.9999]$ and is mapped to a radian value in the range $[0 \ 2\pi]$.

Return $\sin(x)$.

Return $\sin(x)$

Parameters

- `[in]` `x`: Scaled input value in radians.

Parameters

- `[in]` `x`: Scaled input value in radians

group **groupFastMath**

This set of functions provides a fast approximation to sine, cosine, and square root. As compared to most of the other functions in the NMSIS math library, the fast math functions operate on individual values and not arrays. There are separate functions for Q15, Q31, and floating-point data.

3.3.3 Complex Math Functions

Complex Conjugate

void **riscv_cmplx_conj_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t numSamples)

void **riscv_cmplx_conj_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t numSamples)

void **riscv_cmplx_conj_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t numSamples)

group **cmplx_conj**

Conjugates the elements of a complex data vector.

The pSrc points to the source data and pDst points to the destination data where the result should be written. numSamples specifies the number of complex samples and the data in each array is stored in an interleaved fashion (real, imag, real, imag, ...). Each array has a total of 2*numSamples values.

The underlying algorithm is used:

There are separate functions for floating-point, Q15, and Q31 data types.

Functions

void **riscv_cmplx_conj_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t numSamples)

Floating-point complex conjugate.

Return none

Parameters

- [in] pSrc: points to the input vector
- [out] pDst: points to the output vector
- [in] numSamples: number of samples in each vector

void **riscv_cmplx_conj_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t numSamples)

Q15 complex conjugate.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q15 value -1 (0x8000) is saturated to the maximum allowable positive value 0x7FFF.

Parameters

- [in] pSrc: points to the input vector
- [out] pDst: points to the output vector
- [in] numSamples: number of samples in each vector

void **riscv_cmplx_conj_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t numSamples)

Q31 complex conjugate.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. The Q31 value -1 (0x80000000) is saturated to the maximum allowable positive value 0x7FFFFFFF.

Parameters

- [in] `pSrc`: points to the input vector
- [out] `pDst`: points to the output vector
- [in] `numSamples`: number of samples in each vector

Complex Dot Product

```
void riscv_cmplx_dot_prod_f32 (const float32_t *pSrcA, const float32_t *pSrcB, uint32_t num-  
Samples, float32_t *realResult, float32_t *imagResult)
```

```
void riscv_cmplx_dot_prod_q15 (const q15_t *pSrcA, const q15_t *pSrcB, uint32_t numSamples,  
q31_t *realResult, q31_t *imagResult)
```

```
void riscv_cmplx_dot_prod_q31 (const q31_t *pSrcA, const q31_t *pSrcB, uint32_t numSamples,  
q63_t *realResult, q63_t *imagResult)
```

group **cmplx_dot_prod**

Computes the dot product of two complex vectors. The vectors are multiplied element-by-element and then summed.

The `pSrcA` points to the first complex input vector and `pSrcB` points to the second complex input vector. `numSamples` specifies the number of complex samples and the data in each array is stored in an interleaved fashion (real, imag, real, imag, ...). Each array has a total of $2 * \text{numSamples}$ values.

The underlying algorithm is used:

There are separate functions for floating-point, Q15, and Q31 data types.

Functions

```
void riscv_cmplx_dot_prod_f32 (const float32_t *pSrcA, const float32_t *pSrcB, uint32_t  
numSamples, float32_t *realResult, float32_t *imagResult)
```

Floating-point complex dot product.

Return none

Parameters

- [in] `pSrcA`: points to the first input vector
- [in] `pSrcB`: points to the second input vector
- [in] `numSamples`: number of samples in each vector
- [out] `realResult`: real part of the result returned here
- [out] `imagResult`: imaginary part of the result returned here

```
void riscv_cmplx_dot_prod_q15 (const q15_t *pSrcA, const q15_t *pSrcB, uint32_t num-  
Samples, q31_t *realResult, q31_t *imagResult)
```

Q15 complex dot product.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The intermediate 1.15 by 1.15 multiplications are performed with full precision and yield a 2.30 result. These are accumulated in a 64-bit accumulator with 34.30 precision. As a final step, the accumulators are converted to 8.24 format. The return results `realResult` and `imagResult` are in 8.24 format.

Parameters

- [in] `pSrcA`: points to the first input vector
- [in] `pSrcB`: points to the second input vector
- [in] `numSamples`: number of samples in each vector
- [out] `realResult`: real part of the result returned here
- [out] `imagResult`: imaginary part of the result returned here

void **riscv_cmplx_dot_prod_q31**(const q31_t **pSrcA*, const q31_t **pSrcB*, uint32_t *numSamples*, q63_t **realResult*, q63_t **imagResult*)

Q31 complex dot product.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The intermediate 1.31 by 1.31 multiplications are performed with 64-bit precision and then shifted to 16.48 format. The internal real and imaginary accumulators are in 16.48 format and provide 15 guard bits. Additions are nonsaturating and no overflow will occur as long as `numSamples` is less than 32768. The return results `realResult` and `imagResult` are in 16.48 format. Input down scaling is not required.

Parameters

- [in] `pSrcA`: points to the first input vector
- [in] `pSrcB`: points to the second input vector
- [in] `numSamples`: number of samples in each vector
- [out] `realResult`: real part of the result returned here
- [out] `imagResult`: imaginary part of the result returned here

Complex Magnitude

void **riscv_cmplx_mag_f32**(const float32_t **pSrc*, float32_t **pDst*, uint32_t *numSamples*)

void **riscv_cmplx_mag_q15**(const q15_t **pSrc*, q15_t **pDst*, uint32_t *numSamples*)

void **riscv_cmplx_mag_q31**(const q31_t **pSrc*, q31_t **pDst*, uint32_t *numSamples*)

group **cmplx_mag**

Computes the magnitude of the elements of a complex data vector.

The `pSrc` points to the source data and `pDst` points to the where the result should be written. `numSamples` specifies the number of complex samples in the input array and the data is stored in an interleaved fashion (real, imag, real, imag, ...). The input array has a total of $2 * \text{numSamples}$ values; the output array has a total of `numSamples` values.

The underlying algorithm is used:

There are separate functions for floating-point, Q15, and Q31 data types.

Functions

void **riscv_cmplx_mag_f32**(const float32_t **pSrc*, float32_t **pDst*, uint32_t *numSamples*)

Floating-point complex magnitude.

Return none

Parameters

- [in] `pSrc`: points to input vector
- [out] `pDst`: points to output vector
- [in] `numSamples`: number of samples in each vector

void **riscv_cmplx_mag_q15** (const q15_t **pSrc*, q15_t **pDst*, uint32_t *numSamples*)
Q15 complex magnitude.

Return none

Scaling and Overflow Behavior The function implements 1.15 by 1.15 multiplications and finally output is converted into 2.14 format.

Parameters

- [in] `pSrc`: points to input vector
- [out] `pDst`: points to output vector
- [in] `numSamples`: number of samples in each vector

void **riscv_cmplx_mag_q31** (const q31_t **pSrc*, q31_t **pDst*, uint32_t *numSamples*)
Q31 complex magnitude.

Return none

Scaling and Overflow Behavior The function implements 1.31 by 1.31 multiplications and finally output is converted into 2.30 format. Input down scaling is not required.

Parameters

- [in] `pSrc`: points to input vector
- [out] `pDst`: points to output vector
- [in] `numSamples`: number of samples in each vector

Complex Magnitude Squared

void **riscv_cmplx_mag_squared_f32** (const float32_t **pSrc*, float32_t **pDst*, uint32_t *numSamples*)

void **riscv_cmplx_mag_squared_q15** (const q15_t **pSrc*, q15_t **pDst*, uint32_t *numSamples*)

void **riscv_cmplx_mag_squared_q31** (const q31_t **pSrc*, q31_t **pDst*, uint32_t *numSamples*)

group **cmplx_mag_squared**

Computes the magnitude squared of the elements of a complex data vector.

The `pSrc` points to the source data and `pDst` points to the where the result should be written. `numSamples` specifies the number of complex samples in the input array and the data is stored in an interleaved fashion (real, imag, real, imag, ...). The input array has a total of $2 \times \text{numSamples}$ values; the output array has a total of `numSamples` values.

The underlying algorithm is used:

There are separate functions for floating-point, Q15, and Q31 data types.

Functions

void **riscv_cmplx_mag_squared_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t numSamples)

Floating-point complex magnitude squared.

Return none

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] numSamples: number of samples in each vector

void **riscv_cmplx_mag_squared_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t numSamples)

Q15 complex magnitude squared.

Return none

Scaling and Overflow Behavior The function implements 1.15 by 1.15 multiplications and finally output is converted into 3.13 format.

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] numSamples: number of samples in each vector

void **riscv_cmplx_mag_squared_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t numSamples)

Q31 complex magnitude squared.

Return none

Scaling and Overflow Behavior The function implements 1.31 by 1.31 multiplications and finally output is converted into 3.29 format. Input down scaling is not required.

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] numSamples: number of samples in each vector

Complex-by-Complex Multiplication

void **riscv_cmplx_mult_cmplx_f32** (const float32_t *pSrcA, const float32_t *pSrcB, float32_t *pDst, uint32_t numSamples)

void **riscv_cmplx_mult_cmplx_q15** (const q15_t *pSrcA, const q15_t *pSrcB, q15_t *pDst, uint32_t numSamples)

void **riscv_cmplx_mult_cmplx_q31** (const q31_t *pSrcA, const q31_t *pSrcB, q31_t *pDst, uint32_t numSamples)

group CmplxByCmplxMult

Multiplies a complex vector by another complex vector and generates a complex result. The data in the complex arrays is stored in an interleaved fashion (real, imag, real, imag, ...). The parameter `numSamples` represents the number of complex samples processed. The complex arrays have a total of $2 * \text{numSamples}$ real values.

The underlying algorithm is used:

There are separate functions for floating-point, Q15, and Q31 data types.

Functions

void **riscv_cmplx_mult_cmplx_f32** (const float32_t *pSrcA, const float32_t *pSrcB,
float32_t *pDst, uint32_t numSamples)
Floating-point complex-by-complex multiplication.

Return none

Parameters

- [in] pSrcA: points to first input vector
- [in] pSrcB: points to second input vector
- [out] pDst: points to output vector
- [in] numSamples: number of samples in each vector

void **riscv_cmplx_mult_cmplx_q15** (const q15_t *pSrcA, const q15_t *pSrcB, q15_t *pDst,
uint32_t numSamples)
Q15 complex-by-complex multiplication.

Return none

Scaling and Overflow Behavior The function implements 1.15 by 1.15 multiplications and finally output is converted into 3.13 format.

Parameters

- [in] pSrcA: points to first input vector
- [in] pSrcB: points to second input vector
- [out] pDst: points to output vector
- [in] numSamples: number of samples in each vector

void **riscv_cmplx_mult_cmplx_q31** (const q31_t *pSrcA, const q31_t *pSrcB, q31_t *pDst,
uint32_t numSamples)
Q31 complex-by-complex multiplication.

Return none

Scaling and Overflow Behavior The function implements 1.31 by 1.31 multiplications and finally output is converted into 3.29 format. Input down scaling is not required.

Parameters

- [in] pSrcA: points to first input vector
- [in] pSrcB: points to second input vector
- [out] pDst: points to output vector

- [in] numSamples: number of samples in each vector

Complex-by-Real Multiplication

```
void riscv_cmplx_mult_real_f32 (const float32_t *pSrcCmplx, const float32_t *pSrcReal,
                                float32_t *pCmplxDst, uint32_t numSamples)
```

```
void riscv_cmplx_mult_real_q15 (const q15_t *pSrcCmplx, const q15_t *pSrcReal, q15_t *pCmplxDst, uint32_t numSamples)
```

```
void riscv_cmplx_mult_real_q31 (const q31_t *pSrcCmplx, const q31_t *pSrcReal, q31_t *pCmplxDst, uint32_t numSamples)
```

group CmplxByRealMult

Multiplies a complex vector by a real vector and generates a complex result. The data in the complex arrays is stored in an interleaved fashion (real, imag, real, imag, ...). The parameter numSamples represents the number of complex samples processed. The complex arrays have a total of 2*numSamples real values while the real array has a total of numSamples real values.

The underlying algorithm is used:

There are separate functions for floating-point, Q15, and Q31 data types.

Functions

```
void riscv_cmplx_mult_real_f32 (const float32_t *pSrcCmplx, const float32_t *pSrcReal,
                                float32_t *pCmplxDst, uint32_t numSamples)
```

Floating-point complex-by-real multiplication.

Return none

Parameters

- [in] pSrcCmplx: points to complex input vector
- [in] pSrcReal: points to real input vector
- [out] pCmplxDst: points to complex output vector
- [in] numSamples: number of samples in each vector

```
void riscv_cmplx_mult_real_q15 (const q15_t *pSrcCmplx, const q15_t *pSrcReal, q15_t *pCmplxDst, uint32_t numSamples)
```

Q15 complex-by-real multiplication.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] pSrcCmplx: points to complex input vector
- [in] pSrcReal: points to real input vector
- [out] pCmplxDst: points to complex output vector
- [in] numSamples: number of samples in each vector

```
void riscv_cmplx_mult_real_q31 (const q31_t *pSrcCmplx, const q31_t *pSrcReal, q31_t
                                *pCmplxDst, uint32_t numSamples)
```

Q31 complex-by-real multiplication.

Return none

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range[0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrcCmplx: points to complex input vector
- [in] pSrcReal: points to real input vector
- [out] pCmplxDst: points to complex output vector
- [in] numSamples: number of samples in each vector

group **groupCmplxMath**

This set of functions operates on complex data vectors. The data in the complex arrays is stored in an interleaved fashion (real, imag, real, imag, ...). In the API functions, the number of samples in a complex array refers to the number of complex values; the array contains twice this number of real values.

3.3.4 Filtering Functions

High Precision Q31 Biquad Cascade Filter

```
void riscv_biquad_cas_df1_32x64_init_q31 (riscv_biquad_cas_df1_32x64_ins_q31 *S, uint8_t
                                         numStages, const q31_t *pCoeffs, q63_t *pState,
                                         uint8_t postShift)

void riscv_biquad_cas_df1_32x64_q31 (const riscv_biquad_cas_df1_32x64_ins_q31 *S, const
                                     q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
```

group **BiquadCascadeDF1_32x64**

This function implements a high precision Biquad cascade filter which operates on Q31 data values. The filter coefficients are in 1.31 format and the state variables are in 1.63 format. The double precision state variables reduce quantization noise in the filter and provide a cleaner output. These filters are particularly useful when implementing filters in which the singularities are close to the unit circle. This is common for low pass or high pass filters with very low cutoff frequencies.

The function operates on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` and `pDst` points to input and output arrays containing `blockSize` Q31 values.

Algorithm Each Biquad stage implements a second order filter using the difference equation: A Direct Form I algorithm is used with 5 coefficients and 4 state variables per stage. Coefficients `b0`, `b1` and `b2` multiply the input signal $x[n]$ and are referred to as the feedforward coefficients. Coefficients `a1` and `a2` multiply the output signal $y[n]$ and are referred to as the feedback coefficients. Pay careful attention to the sign of the feedback coefficients. Some design tools use the difference equation In this case the feedback coefficients `a1` and `a2` must be negated when used with the NMSIS DSP Library.

Higher order filters are realized as a cascade of second order sections. `numStages` refers to the number of second order stages used. For example, an 8th order filter would be realized with `numStages=4` second order stages. A 9th order filter would be realized with `numStages=5` second order stages with the coefficients for one of the stages configured as a first order filter (`b2=0` and `a2=0`).

The `pState` points to state variables array. Each Biquad stage has 4 state variables $x[n-1]$, $x[n-2]$, $y[n-1]$, and $y[n-2]$ and each state variable in 1.63 format to improve precision. The state variables are arranged in the array as:

The 4 state variables for stage 1 are first, then the 4 state variables for stage 2, and so on. The state array has a total length of $4 * \text{numStages}$ values of data in 1.63 format. The state variables are updated after each block of data is processed, the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable arrays cannot be shared.

Init Function There is also an associated initialization function which performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numStages`, `pCoeffs`, `postShift`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros before static

initialization. For example, to statically initialize the filter instance structure use where `numStages` is the number of Biquad stages in the filter; `pState` is the address of the state buffer; `pCoeffs` is the address of the coefficient buffer; `postShift` shift to be applied which is described in detail below.

Fixed-Point Behavior Care must be taken while using Biquad Cascade 32x64 filter function. Following issues must be considered:

- Scaling of coefficients
- Filter gain
- Overflow and saturation

Filter coefficients are represented as fractional values and restricted to lie in the range $[-1 \ +1)$. The processing function has an additional scaling parameter `postShift` which allows the filter coefficients to exceed the range $[-1 \ +1)$. At the output of the filter's accumulator is a shift register which shifts the result by `postShift` bits. This essentially scales the filter coefficients by $2^{\text{postShift}}$. For example, to realize the coefficients set the Coefficient array to: and set `postShift=1`

The second thing to keep in mind is the gain through the filter. The frequency response of a Biquad filter is a function of its coefficients. It is possible for the gain through the filter to exceed 1.0 meaning that the filter increases the amplitude of certain frequencies. This means that an input signal with amplitude < 1.0 may result in an output > 1.0 and these are saturated or overflowed based on the implementation of the filter. To avoid this behavior the filter needs to be scaled down such that its peak gain < 1.0 or the input signal must be scaled down so that the combination of input and filter are never overflowed.

The third item to consider is the overflow and saturation behavior of the fixed-point Q31 version. This is described in the function specific documentation below.

Functions

```
void riscv_biquad_cas_df1_32x64_init_q31 (riscv_biquad_cas_df1_32x64_ins_q31 *S,
                                         uint8_t numStages, const q31_t *pCoeffs,
                                         q63_t *pState, uint8_t postShift)
```

Initialization function for the Q31 Biquad cascade 32x64 filter.

Return none

Coefficient and State Ordering The coefficients are stored in the array `pCoeffs` in the following order: where `b1x` and `a1x` are the coefficients for the first stage, `b2x` and `a2x` are the coefficients for the second stage, and so on. The `pCoeffs` array contains a total of `5*numStages` values.

The `pState` points to state variables array and size of each state variable is 1.63 format. Each Biquad stage has 4 state variables `x[n-1]`, `x[n-2]`, `y[n-1]`, and `y[n-2]`. The state variables are arranged in the state array as: The 4 state variables for stage 1 are first, then the 4 state variables for stage 2, and so on. The state array has a total length of `4*numStages` values. The state variables are updated after each block of data is processed; the coefficients are untouched.

Parameters

- `[inout] S`: points to an instance of the high precision Q31 Biquad cascade filter structure
- `[in] numStages`: number of 2nd order stages in the filter
- `[in] pCoeffs`: points to the filter coefficients
- `[in] pState`: points to the state buffer
- `[in] postShift`: Shift to be applied after the accumulator. Varies according to the coefficients format

```
void riscv_biquad_cas_df1_32x64_q31 (const riscv_biquad_cas_df1_32x64_ins_q31 *S,
                                     const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
Processing function for the Q31 Biquad cascade 32x64 filter.
```

Return none

Details The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by 2 bits and lie in the range $[-0.25 +0.25]$. After all 5 multiply-accumulates are performed, the 2.62 accumulator is shifted by `postShift` bits and the result truncated to 1.31 format by discarding the low 32 bits.

Two related functions are provided in the NMSIS DSP library.

- `riscv_biquad_cascade_df1_q31()` implements a Biquad cascade with 32-bit coefficients and state variables with a Q63 accumulator.
- `riscv_biquad_cascade_df1_fast_q31()` implements a Biquad cascade with 32-bit coefficients and state variables with a Q31 accumulator.

Parameters

- `[in] S`: points to an instance of the high precision Q31 Biquad cascade filter
- `[in] pSrc`: points to the block of input data
- `[out] pDst`: points to the block of output data
- `[in] blockSize`: number of samples to process

Biquad Cascade IIR Filters Using Direct Form I Structure

```
void riscv_biquad_cascade_df1_f32 (const riscv_biquad_casd_df1_inst_f32 *S, const float32_t
                                   *pSrc, float32_t *pDst, uint32_t blockSize)
void riscv_biquad_cascade_df1_fast_q15 (const riscv_biquad_casd_df1_inst_q15 *S, const
                                         q15_t *pSrc, q15_t *pDst, uint32_t blockSize)
```

```

void riscv_biquad_cascade_df1_fast_q31 (const riscv_biquad_casd_df1_inst_q31 *S, const
                                         q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
void riscv_biquad_cascade_df1_init_f32 (riscv_biquad_casd_df1_inst_f32 *S, uint8_t num-
                                         Stages, const float32_t *pCoeffs, float32_t *pState)
void riscv_biquad_cascade_df1_init_q15 (riscv_biquad_casd_df1_inst_q15 *S, uint8_t num-
                                         Stages, const q15_t *pCoeffs, q15_t *pState, int8_t
                                         postShift)
void riscv_biquad_cascade_df1_init_q31 (riscv_biquad_casd_df1_inst_q31 *S, uint8_t num-
                                         Stages, const q31_t *pCoeffs, q31_t *pState, int8_t
                                         postShift)
void riscv_biquad_cascade_df1_q15 (const riscv_biquad_casd_df1_inst_q15 *S, const q15_t
                                   *pSrc, q15_t *pDst, uint32_t blockSize)
void riscv_biquad_cascade_df1_q31 (const riscv_biquad_casd_df1_inst_q31 *S, const q31_t
                                   *pSrc, q31_t *pDst, uint32_t blockSize)

```

group BiquadCascadeDF1

This set of functions implements arbitrary order recursive (IIR) filters. The filters are implemented as a cascade of second order Biquad sections. The functions support Q15, Q31 and floating-point data types. Fast version of Q15 and Q31 also available.

The functions operate on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` points to the array of input data and `pDst` points to the array of output data. Both arrays contain `blockSize` values.

Algorithm Each Biquad stage implements a second order filter using the difference equation: A Direct Form I algorithm is used with 5 coefficients and 4 state variables per stage. Coefficients b_0 , b_1 and b_2 multiply the input signal $x[n]$ and are referred to as the feedforward coefficients. Coefficients a_1 and a_2 multiply the output signal $y[n]$ and are referred to as the feedback coefficients. Pay careful attention to the sign of the feedback coefficients. Some design tools use the difference equation In this case the feedback coefficients a_1 and a_2 must be negated when used with the NMSIS DSP

Library.

Higher order filters are realized as a cascade of second order sections. `numStages` refers to the

number of second order stages used. For example, an 8th order filter would be realized with `numStages=4` second order stages. A 9th order filter would be realized with `numStages=5` second order stages with the coefficients for one of the stages configured as a first order filter (`b2=0` and `a2=0`).

The `pState` points to state variables array. Each Biquad stage has 4 state variables $x[n-1]$, $x[n-2]$, $y[n-1]$, and $y[n-2]$. The state variables are arranged in the `pState` array as:

The 4 state variables for stage 1 are first, then the 4 state variables for stage 2, and so on. The state array has a total length of $4 * \text{numStages}$ values. The state variables are updated after each block of data is processed, the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable arrays cannot be shared. There are separate instance structure declarations for each of the 3 supported data types.

Init Function There is also an associated initialization function for each data type. The initialization function performs following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numStages`, `pCoeffs`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros before static initialization. The code below statically initializes each of the 3 different data type filter instance structures where `numStages` is the number of Biquad stages in the filter; `pState` is the address of the state buffer; `pCoeffs` is the address of the coefficient buffer; `postShift` shift to be applied.

Fixed-Point Behavior Care must be taken when using the Q15 and Q31 versions of the Biquad Cascade filter functions. Following issues must be considered:

- Scaling of coefficients
- Filter gain
- Overflow and saturation

Scaling of coefficients Filter coefficients are represented as fractional values and coefficients are restricted to lie in the range $[-1 \ +1)$. The fixed-point functions have an additional scaling parameter `postShift` which allow the filter coefficients to exceed the range $[-1 \ +1)$. At the output of the filter's accumulator is a shift register which shifts the result by `postShift` bits. This essentially scales the filter coefficients by $2^{\text{postShift}}$. For example, to realize the coefficients set the `pCoeffs` array to: and set

postShift=1

Filter gain The frequency response of a Biquad filter is a function of its coefficients. It is possible for the gain through the filter to exceed 1.0 meaning that the filter increases the amplitude of certain frequencies. This means that an input signal with amplitude < 1.0 may result in an output > 1.0 and these are saturated or overflowed based on the implementation of the filter. To avoid this behavior the filter needs to be scaled down such that its peak gain < 1.0 or the input signal must be scaled down so that the combination of input and filter are never overflowed.

Overflow and saturation For Q15 and Q31 versions, it is described separately as part of the function specific documentation below.

Functions

void **riscv_biquad_cascade_df1_f32** (const riscv_biquad_casd_df1_inst_f32 *S, const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)
Processing function for the floating-point Biquad cascade filter.

Return none

Parameters

- [in] S: points to an instance of the floating-point Biquad cascade structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

void **riscv_biquad_cascade_df1_fast_q15** (const riscv_biquad_casd_df1_inst_q15 *S, const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)
Processing function for the Q15 Biquad cascade filter (fast variant).

Fast but less precise processing function for the Q15 Biquad cascade filter for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around and distorts the result. In order to avoid overflows completely the input signal must be scaled down by two bits and lie in the range $[-0.25 +0.25]$. The 2.30 accumulator is then shifted by `postShift` bits and the result truncated to 1.15 format by discarding the low 16 bits.

Remark Refer to `riscv_biquad_cascade_df1_q15()` for a slower implementation of this function which uses 64-bit accumulation to avoid wrap around distortion. Both the slow and the fast versions use the same instance structure. Use the function `riscv_biquad_cascade_df1_init_q15()` to initialize the filter structure.

Parameters

- [in] `S`: points to an instance of the Q15 Biquad cascade structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process per call

```
void riscv_biquad_cascade_df1_fast_q31 (const riscv_biquad_casd_df1_inst_q31 *S,
                                         const q31_t *pSrc, q31_t *pDst, uint32_t
                                         blockSize)
```

Processing function for the Q31 Biquad cascade filter (fast variant).

Fast but less precise processing function for the Q31 Biquad cascade filter for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This function is optimized for speed at the expense of fixed-point precision and overflow protection. The result of each 1.31×1.31 multiplication is truncated to 2.30 format. These intermediate results are added to a 2.30 accumulator. Finally, the accumulator is saturated and converted to a 1.31 result. The fast version has the same overflow behavior as the standard version and provides less precision since it discards the low 32 bits of each multiplication result. In order to avoid overflows completely the input signal must be scaled down by two bits and lie in the range $[-0.25 +0.25]$. Use the initialization function `riscv_biquad_cascade_df1_init_q31()` to initialize filter structure.

Remark Refer to `riscv_biquad_cascade_df1_q31()` for a slower implementation of this function which uses 64-bit accumulation to provide higher precision. Both the slow and the fast versions use the same instance structure. Use the function `riscv_biquad_cascade_df1_init_q31()` to initialize the filter structure.

Parameters

- [in] `S`: points to an instance of the Q31 Biquad cascade structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process per call

```
void riscv_biquad_cascade_df1_init_f32 (riscv_biquad_casd_df1_inst_f32 *S, uint8_t num-
                                         Stages, const float32_t *pCoeffs, float32_t
                                         *pState)
```

Initialization function for the floating-point Biquad cascade filter.

The initialization function which must be used is `riscv_biquad_cascade_df1_mve_init_f32`.

Return none

Coefficient and State Ordering The coefficients are stored in the array `pCoeffs` in the following order:

where `b1x` and `a1x` are the coefficients for the first stage, `b2x` and `a2x` are the coefficients for the second stage, and so on. The `pCoeffs` array contains a total of `5*numStages` values.

The `pState` is a pointer to state array. Each Biquad stage has 4 state variables `x[n-1]`, `x[n-2]`, `y[n-1]`, and `y[n-2]`. The state variables are arranged in the `pState` array as: The 4 state variables for stage 1 are first, then the 4 state variables for stage 2, and so on. The state array has a total length of `4*numStages` values. The state variables are updated after each block of data is processed; the coefficients are untouched.

For MVE code, an additional buffer of modified coefficients is required. Its size is `numStages` and each element of this buffer has type `riscv_biquad_mod_coef_f32`. So, its total size is `32*numStages` `float32_t` elements.

Parameters

- `[inout]` `S`: points to an instance of the floating-point Biquad cascade structure.
- `[in]` `numStages`: number of 2nd order stages in the filter.
- `[in]` `pCoeffs`: points to the filter coefficients.
- `[in]` `pState`: points to the state buffer.

```
void riscv_biquad_cascade_df1_init_q15(riscv_biquad_casd_df1_inst_q15 *S, uint8_t
                                     numStages, const q15_t *pCoeffs, q15_t
                                     *pState, int8_t postShift)
```

Initialization function for the Q15 Biquad cascade filter.

Return none

Coefficient and State Ordering The coefficients are stored in the array `pCoeffs` in the following order:

where `b1x` and `a1x` are the coefficients for the first stage, `b2x` and `a2x` are the coefficients for the second stage, and so on. The `pCoeffs` array contains a total of `6*numStages` values. The zero coefficient between `b1` and `b2` facilities use of 16-bit SIMD instructions on the RISC-V Core with DSP.

The state variables are stored in the array `pState`. Each Biquad stage has 4 state variables `x[n-1]`, `x[n-2]`, `y[n-1]`, and `y[n-2]`. The state variables are arranged in the `pState` array as: The 4 state variables for stage 1 are first, then the 4 state variables for stage 2, and so on. The state array has a total length of `4*numStages` values. The state variables are updated after each block of data is processed; the coefficients are untouched.

Parameters

- `[inout]` `S`: points to an instance of the Q15 Biquad cascade structure.
- `[in]` `numStages`: number of 2nd order stages in the filter.
- `[in]` `pCoeffs`: points to the filter coefficients.
- `[in]` `pState`: points to the state buffer.
- `[in]` `postShift`: Shift to be applied to the accumulator result. Varies according to the coefficients format

```
void riscv_biquad_cascade_df1_init_q31(riscv_biquad_casd_df1_inst_q31 *S, uint8_t
                                     numStages, const q31_t *pCoeffs, q31_t
                                     *pState, int8_t postShift)
```

Initialization function for the Q31 Biquad cascade filter.

Return none

Coefficient and State Ordering The coefficients are stored in the array `pCoeffs` in the following order: where `b1x` and `a1x` are the coefficients for the first stage, `b2x` and `a2x` are the coefficients for the second stage, and so on. The `pCoeffs` array contains a total of `5*numStages` values.

The `pState` points to state variables array. Each Biquad stage has 4 state variables `x[n-1]`, `x[n-2]`, `y[n-1]`, and `y[n-2]`. The state variables are arranged in the `pState` array as: The 4 state variables for stage 1 are first, then the 4 state variables for stage 2, and so on. The state array has a total length of `4*numStages` values. The state variables are updated after each block of data is processed; the coefficients are untouched.

Parameters

- [inout] `S`: points to an instance of the Q31 Biquad cascade structure.
- [in] `numStages`: number of 2nd order stages in the filter.
- [in] `pCoeffs`: points to the filter coefficients.
- [in] `pState`: points to the state buffer.
- [in] `postShift`: Shift to be applied after the accumulator. Varies according to the coefficients format

```
void riscv_biquad_cascade_df1_q15(const riscv_biquad_casd_df1_inst_q15 *S, const
                                q15_t *pSrc, q15_t *pDst, uint32_t blockSize)
```

Processing function for the Q15 Biquad cascade filter.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. The accumulator is then shifted by `postShift` bits to truncate the result to 1.15 format by discarding the low 16 bits. Finally, the result is saturated to 1.15 format.

Remark Refer to `riscv_biquad_cascade_df1_fast_q15()` for a faster but less precise implementation of this filter.

Parameters

- [in] `S`: points to an instance of the Q15 Biquad cascade structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the location where the output result is written
- [in] `blockSize`: number of samples to process

```
void riscv_biquad_cascade_df1_q31(const riscv_biquad_casd_df1_inst_q31 *S, const
                                q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
```

Processing function for the Q31 Biquad cascade filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by 2 bits and

lie in the range $[-0.25, +0.25]$. After all 5 multiply-accumulates are performed, the 2.62 accumulator is shifted by `postShift` bits and the result truncated to 1.31 format by discarding the low 32 bits.

Remark Refer to `riscv_biquad_cascade_df1_fast_q31()` for a faster but less precise implementation of this filter.

Parameters

- [in] `S`: points to an instance of the Q31 Biquad cascade structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process

Biquad Cascade IIR Filters Using a Direct Form II Transposed Structure

```

                                     *pState)
LOW_OPTIMIZATION_ENTER void riscv_biquad_cascade_stereo_df2T_f32(const  riscv_biquad_cascade_stereo_df2T_instance_f32 *S,
void riscv_biquad_cascade_stereo_df2T_init_f32(riscv_biquad_cascade_stereo_df2T_instance_f32 *S, uint8_t numStages, const float32_t
                                     *pCoeffs, float32_t *pState)
```

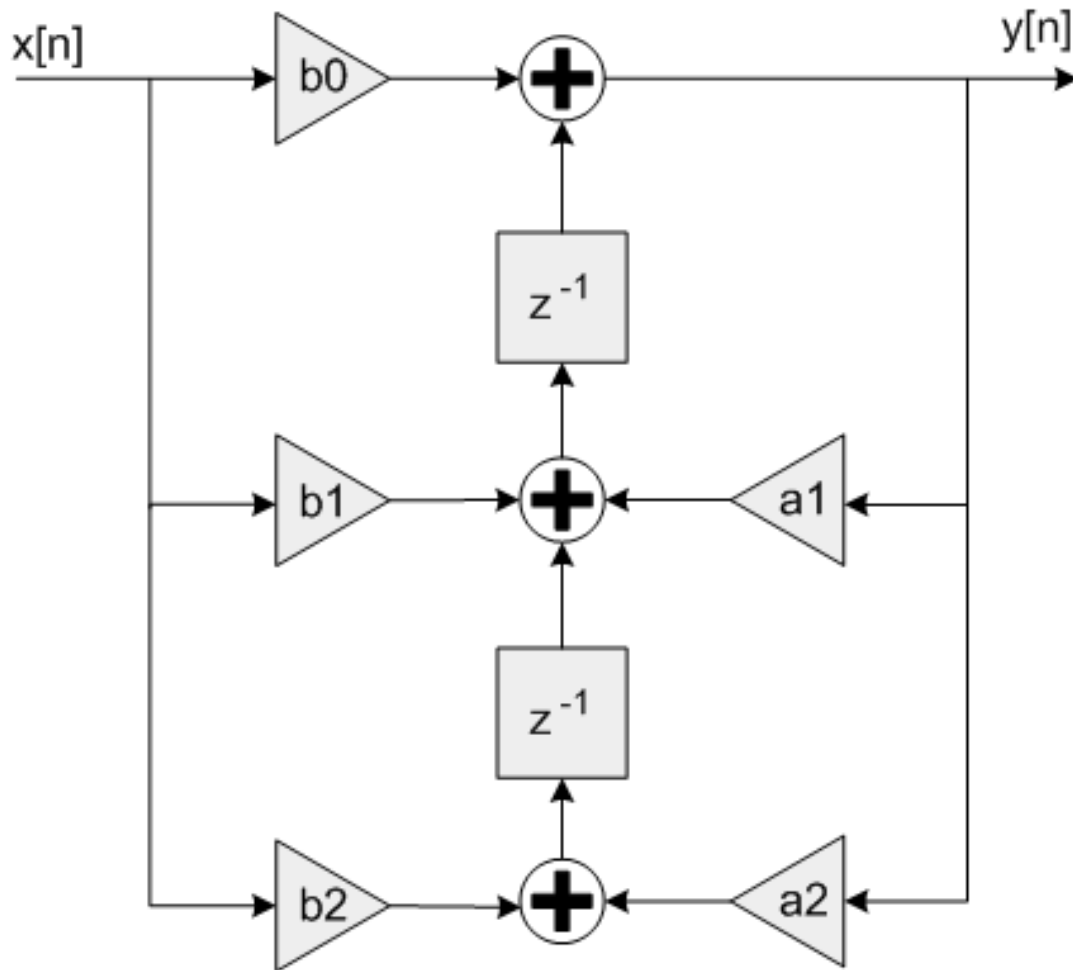

group BiquadCascadeDF2T

This set of functions implements arbitrary order recursive (IIR) filters using a transposed direct form II structure. The filters are implemented as a cascade of second order Biquad sections. These functions provide a slight memory savings as compared to the direct form I Biquad filter functions. Only floating-point data is supported.

This function operate on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` points to the array of input data and `pDst` points to the array of output data. Both arrays contain `blockSize` values.

Algorithm Each Biquad stage implements a second order filter using the difference equation: where `d1` and `d2` represent the two state values.

A Biquad filter using a transposed Direct Form II structure is shown below. Coefficients `b0`, `b1`, and `b2` multiply the input signal $x[n]$ and are referred to as the feedforward coefficients. Coefficients `a1` and `a2` multiply the output signal $y[n]$ and are referred to as the feedback coefficients. Pay careful attention to the sign of the feedback coefficients. Some design tools flip the sign of the feedback coefficients: In this case the feedback coefficients `a1` and `a2` must be negated when used with the NMSIS DSP Library.

Higher order filters are realized as a cascade of second order sections. `numStages` refers to the number of second order stages used. For example, an 8th order filter would be realized with `numStages=4` second order stages. A 9th order filter would be realized with `numStages=5` second order stages with the coefficients for one of the stages configured as a first order filter (`b2=0` and `a2=0`).

`pState` points to the state variable array. Each Biquad stage has 2 state variables `d1` and `d2`. The state variables are arranged in the `pState` array as: where `d1x` refers to the state variables for the first Biquad and `d2x` refers to the state variables for the second Biquad. The state array has a total length of $2 \times \text{numStages}$ values. The state variables are updated after each block of data is processed; the coefficients are untouched.

The NMSIS library contains Biquad filters in both Direct Form I and transposed Direct Form II. The advantage of the Direct Form I structure is that it is numerically more robust for fixed-point data types. That is why the Direct Form I structure supports Q15 and Q31 data types. The transposed Direct Form II structure, on the other hand, requires a wide dynamic range for the state variables `d1` and `d2`. Because of this, the NMSIS library only has a floating-point version of the Direct Form II Biquad. The advantage of the Direct Form II Biquad is that it requires half the number of state variables, 2 rather than 4, per Biquad stage.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable arrays cannot be shared.

Init Functions There is also an associated initialization function. The initialization function performs following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numStages`, `pCoeffs`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros before static initialization. For example, to statically initialize the instance structure use where `numStages` is the number of Biquad stages in the filter; `pState` is the address of the state buffer. `pCoeffs` is the address of the coefficient buffer;

Functions

LOW_OPTIMIZATION_ENTER `void riscv_biquad_cascade_df2T_f32 (const riscv_biquad_cascade_`
Processing function for the floating-point transposed direct form II Biquad cascade filter.

Return none

Parameters

- [in] `S`: points to an instance of the filter data structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process

LOW_OPTIMIZATION_ENTER `void riscv_biquad_cascade_df2T_f64 (const riscv_biquad_cascade_`
Processing function for the floating-point transposed direct form II Biquad cascade filter.

Return none

Parameters

- [in] `S`: points to an instance of the filter data structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process

`void riscv_biquad_cascade_df2T_init_f32 (riscv_biquad_cascade_df2T_instance_f32 *S,`
`uint8_t numStages, const float32_t *pCoeffs,`
`float32_t *pState)`

Initialization function for the floating-point transposed direct form II Biquad cascade filter.

For Neon version, this array is bigger. If `numstages = 4x + y`, then the array has size: `32*x + 5*y` and it must be initialized using the function `riscv_biquad_cascade_df2T_compute_coefs_f32` which is taking the standard array coefficient as parameters.

Return none

Coefficient and State Ordering The coefficients are stored in the array `pCoeffs` in the following order in the not Neon version.

where `b1x` and `a1x` are the coefficients for the first stage, `b2x` and `a2x` are the coefficients for the second stage, and so on. The `pCoeffs` array contains a total of `5*numStages` values.

Parameters

- [inout] *S*: points to an instance of the filter data structure.
- [in] *numStages*: number of 2nd order stages in the filter.
- [in] *pCoeffs*: points to the filter coefficients.
- [in] *pState*: points to the state buffer.

But, an array of $8 * \text{numStages}$ is a good approximation.

Then, the initialization can be done with:

In this example, *neonCoefs* is a bigger array of size $8 * \text{numStages}$. *coefs* is the standard array:

The *pState* is a pointer to state array. Each Biquad stage has 2 state variables *d1*, and *d2*. The 2 state variables for stage 1 are first, then the 2 state variables for stage 2, and so on. The state array has a total length of $2 * \text{numStages}$ values. The state variables are updated after each block of data is processed; the coefficients are untouched.

```
void riscv_biquad_cascade_df2T_init_f64 (riscv_biquad_cascade_df2T_instance_f64 *S,
                                         uint8_t numStages, const float64_t *pCoeffs,
                                         float64_t *pState)
```

Initialization function for the floating-point transposed direct form II Biquad cascade filter.

Return none

Coefficient and State Ordering The coefficients are stored in the array *pCoeffs* in the following order:

where *b1x* and *a1x* are the coefficients for the first stage, *b2x* and *a2x* are the coefficients for the second stage, and so on. The *pCoeffs* array contains a total of $5 * \text{numStages}$ values.

The *pState* is a pointer to state array. Each Biquad stage has 2 state variables *d1*, and *d2*. The 2 state variables for stage 1 are first, then the 2 state variables for stage 2, and so on. The state array has a total length of $2 * \text{numStages}$ values. The state variables are updated after each block of data is processed; the coefficients are untouched.

Parameters

- [inout] *S*: points to an instance of the filter data structure
- [in] *numStages*: number of 2nd order stages in the filter
- [in] *pCoeffs*: points to the filter coefficients
- [in] *pState*: points to the state buffer

```
LOW_OPTIMIZATION_ENTER void riscv_biquad_cascade_stereo_df2T_f32 (const riscv_biquad_cascade_df2T_instance_f32 *S,
```

Processing function for the floating-point transposed direct form II Biquad cascade filter.

Processing function for the floating-point transposed direct form II Biquad cascade filter. 2 channels.

Return none

Parameters

- [in] *S*: points to an instance of the filter data structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

```
void riscv_biquad_cascade_stereo_df2T_init_f32 (riscv_biquad_cascade_stereo_df2T_instance_f32
                                                *S, uint8_t numStages, const
                                                float32_t *pCoeffs, float32_t
                                                *pState)
```

Initialization function for the floating-point transposed direct form II Biquad cascade filter.

Return none

Coefficient and State Ordering The coefficients are stored in the array `pCoeffs` in the following order:

where `b1x` and `a1x` are the coefficients for the first stage, `b2x` and `a2x` are the coefficients for the second stage, and so on. The `pCoeffs` array contains a total of $5 \times \text{numStages}$ values.

The `pState` is a pointer to state array. Each Biquad stage has 2 state variables `d1`, and `d2` for each channel. The 2 state variables for stage 1 are first, then the 2 state variables for stage 2, and so on. The state array has a total length of $2 \times \text{numStages}$ values. The state variables are updated after each block of data is processed; the coefficients are untouched.

Parameters

- [inout] `S`: points to an instance of the filter data structure.
- [in] `numStages`: number of 2nd order stages in the filter.
- [in] `pCoeffs`: points to the filter coefficients.
- [in] `pState`: points to the state buffer.

Convolution

```
void riscv_conv_f32 (const float32_t *pSrcA, uint32_t srcALen, const float32_t *pSrcB, uint32_t sr-
                    cBLen, float32_t *pDst)
```

```
void riscv_conv_fast_opt_q15 (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB,
                             uint32_t srcBLen, q15_t *pDst, q15_t *pScratch1, q15_t *pScratch2)
```

```
void riscv_conv_fast_q15 (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB, uint32_t sr-
                         cBLen, q15_t *pDst)
```

```
void riscv_conv_fast_q31 (const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB, uint32_t sr-
                         cBLen, q31_t *pDst)
```

```
void riscv_conv_opt_q15 (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB, uint32_t sr-
                       cBLen, q15_t *pDst, q15_t *pScratch1, q15_t *pScratch2)
```

```
void riscv_conv_opt_q7 (const q7_t *pSrcA, uint32_t srcALen, const q7_t *pSrcB, uint32_t srcBLen,
                      q7_t *pDst, q15_t *pScratch1, q15_t *pScratch2)
```

```
void riscv_conv_q15 (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB, uint32_t srcBLen,
                   q15_t *pDst)
```

```
void riscv_conv_q31 (const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB, uint32_t srcBLen,
                   q31_t *pDst)
```

```
void riscv_conv_q7 (const q7_t *pSrcA, uint32_t srcALen, const q7_t *pSrcB, uint32_t srcBLen, q7_t
                  *pDst)
```

group Conv

Convolution is a mathematical operation that operates on two finite length vectors to generate a finite length output vector. Convolution is similar to correlation and is frequently used in filtering and data analysis. The NMSIS DSP library contains functions for convolving Q7, Q15, Q31, and floating-point data types. The library also provides fast versions of the Q15 and Q31 functions.

Algorithm Let $a[n]$ and $b[n]$ be sequences of length `srcALen` and `srcBLen` samples respectively. Then the convolution

$$c[n] = \sum_{k=0}^{\text{srcALen}} a[k]b[n-k]$$

is defined as

Note that $c[n]$ is of length `srcALen + srcBLen - 1` and is defined over the interval $n=0, 1, 2, \dots, \text{srcALen} + \text{srcBLen} - 2$. `pSrcA` points to the first input vector of length `srcALen` and `pSrcB` points to the second input vector of length `srcBLen`. The output result is written to `pDst` and the calling function must allocate `srcALen+srcBLen-1` words for the result.

Conceptually, when two signals $a[n]$ and $b[n]$ are convolved, the signal $b[n]$ slides over $a[n]$. For each offset n , the overlapping portions of $a[n]$ and $b[n]$ are multiplied and summed together.

Note that convolution is a commutative operation:

This means that switching the A and B arguments to the convolution functions has no effect.

Fixed-Point Behavior Convolution requires summing up a large number of intermediate products. As such, the Q7, Q15, and Q31 functions run a risk of overflow and saturation. Refer to the function specific documentation below for further details of the particular algorithm used.

Fast Versions Fast versions are supported for Q31 and Q15. Cycles for Fast versions are less compared to Q31 and Q15 of `conv` and the design requires the input signals should be scaled down to avoid intermediate overflows.

Opt Versions Opt versions are supported for Q15 and Q7. Design uses internal scratch buffer for getting good optimisation. These versions are optimised in cycles and consumes more memory (Scratch memory) compared to Q15 and Q7 versions

Functions

void **riscv_conv_f32** (**const** float32_t *pSrcA, uint32_t srcALen, **const** float32_t *pSrcB, uint32_t srcBLen, float32_t *pDst)

Convolution of floating-point sequences.

Return none

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length `srcALen+srcBLen-1`.

void **riscv_conv_fast_opt_q15** (**const** q15_t *pSrcA, uint32_t srcALen, **const** q15_t *pSrcB, uint32_t srcBLen, q15_t *pDst, q15_t *pScratch1, q15_t *pScratch2)

Convolution of Q15 sequences (fast version).

Convolution of Q15 sequences (fast version) for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. Scale down the inputs by $\log_2(\min(\text{srcALen}, \text{srcBLen}))$ (\log_2 is read as log to the base 2) times to avoid overflows, as maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions are carried internally. The 2.30 accumulator is right shifted by 15 bits and then saturated to 1.15 format to yield the final result.

Remark Refer to `riscv_conv_q15()` for a slower implementation of this function which uses 64-bit accumulation to avoid wrap around distortion.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length `srcALen+srcBLen-1`
- [in] `pScratch1`: points to scratch buffer of size $\max(\text{srcALen}, \text{srcBLen}) + 2 * \min(\text{srcALen}, \text{srcBLen}) - 2$
- [in] `pScratch2`: points to scratch buffer of size $\min(\text{srcALen}, \text{srcBLen})$

```
void riscv_conv_fast_q15(const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB,  
                        uint32_t srcBLen, q15_t *pDst)
```

Convolution of Q15 sequences (fast version).

Convolution of Q15 sequences (fast version) for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. Scale down the inputs by $\log_2(\min(\text{srcALen}, \text{srcBLen}))$ (\log_2 is read as log to the base 2) times to avoid overflows, as maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions are carried internally. The 2.30 accumulator is right shifted by 15 bits and then saturated to 1.15 format to yield the final result.

Remark Refer to `riscv_conv_q15()` for a slower implementation of this function which uses 64-bit accumulation to avoid wrap around distortion.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length `srcALen+srcBLen-1`

```
void riscv_conv_fast_q31(const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB,
                        uint32_t srcBLen, q31_t *pDst)
```

Convolution of Q31 sequences (fast version).

Convolution of Q31 sequences (fast version) for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This function is optimized for speed at the expense of fixed-point precision and overflow protection. The result of each 1.31 x 1.31 multiplication is truncated to 2.30 format. These intermediate results are accumulated in a 32-bit register in 2.30 format. Finally, the accumulator is saturated and converted to a 1.31 result.

The fast version has the same overflow behavior as the standard version but provides less precision since it discards the low 32 bits of each multiplication result. In order to avoid overflows completely the input signals must be scaled down. Scale down the inputs by $\log_2(\min(\text{srcALen}, \text{srcBLen}))$ (\log_2 is read as log to the base 2) times to avoid overflows, as maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions are carried internally.

Remark Refer to `riscv_conv_q31()` for a slower implementation of this function which uses 64-bit accumulation to provide higher precision.

Parameters

- [in] pSrcA: points to the first input sequence.
- [in] srcALen: length of the first input sequence.
- [in] pSrcB: points to the second input sequence.
- [in] srcBLen: length of the second input sequence.
- [out] pDst: points to the location where the output result is written. Length $\text{srcALen} + \text{srcBLen} - 1$.

```
void riscv_conv_opt_q15(const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB, uint32_t
                        srcBLen, q15_t *pDst, q15_t *pScratch1, q15_t *pScratch2)
```

Convolution of Q15 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both inputs are in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. This approach provides 33 guard bits and there is no risk of overflow. The 34.30 result is then truncated to 34.15 format by discarding the low 15 bits and then saturated to 1.15 format.

Remark Refer to `riscv_conv_fast_q15()` for a faster but less precise version of this function.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length $\text{srcALen} + \text{srcBLen} - 1$.
- [in] pScratch1: points to scratch buffer of size $\max(\text{srcALen}, \text{srcBLen}) + 2 * \min(\text{srcALen}, \text{srcBLen}) - 2$.

- [in] pScratch2: points to scratch buffer of size min(srcALen, srcBLen).

void **riscv_conv_opt_q7** (const q7_t *pSrcA, uint32_t srcALen, const q7_t *pSrcB, uint32_t srcBLen, q7_t *pDst, q15_t *pScratch1, q15_t *pScratch2)
Convolution of Q7 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. Both the inputs are represented in 1.7 format and multiplications yield a 2.14 result. The 2.14 intermediate results are accumulated in a 32-bit accumulator in 18.14 format. This approach provides 17 guard bits and there is no risk of overflow as long as $\max(\text{srcALen}, \text{srcBLen}) < 131072$. The 18.14 result is then truncated to 18.7 format by discarding the low 7 bits and then saturated to 1.7 format.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length srcALen+srcBLen-1.
- [in] pScratch1: points to scratch buffer(of type q15_t) of size $\max(\text{srcALen}, \text{srcBLen}) + 2 * \min(\text{srcALen}, \text{srcBLen}) - 2$.
- [in] pScratch2: points to scratch buffer (of type q15_t) of size min(srcALen, srcBLen).

void **riscv_conv_q15** (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB, uint32_t srcBLen, q15_t *pDst)
Convolution of Q15 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both inputs are in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. This approach provides 33 guard bits and there is no risk of overflow. The 34.30 result is then truncated to 34.15 format by discarding the low 15 bits and then saturated to 1.15 format.

Remark Refer to riscv_conv_fast_q15() for a faster but less precise version of this function.

Remark Refer to riscv_conv_opt_q15() for a faster implementation of this function using scratch buffers.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length srcALen+srcBLen-1.

void **riscv_conv_q31** (const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB, uint32_t srcBLen, q31_t *pDst)
Convolution of Q31 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. Scale down the inputs by $\log_2(\min(\text{srcALen}, \text{srcBLen}))$ (\log_2 is read as log to the base 2) times to avoid overflows, as maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions are carried internally. The 2.62 accumulator is right shifted by 31 bits and saturated to 1.31 format to yield the final result.

Remark Refer to `riscv_conv_fast_q31()` for a faster but less precise implementation of this function.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length $\text{srcALen} + \text{srcBLen} - 1$.

void **riscv_conv_q7** (const q7_t *pSrcA, uint32_t srcALen, const q7_t *pSrcB, uint32_t srcBLen, q7_t *pDst)
Convolution of Q7 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. Both the inputs are represented in 1.7 format and multiplications yield a 2.14 result. The 2.14 intermediate results are accumulated in a 32-bit accumulator in 18.14 format. This approach provides 17 guard bits and there is no risk of overflow as long as $\max(\text{srcALen}, \text{srcBLen}) < 131072$. The 18.14 result is then truncated to 18.7 format by discarding the low 7 bits and then saturated to 1.7 format.

Remark Refer to `riscv_conv_opt_q7()` for a faster implementation of this function.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length $\text{srcALen} + \text{srcBLen} - 1$.

Partial Convolution

riscv_status **riscv_conv_partial_f32** (const float32_t *pSrcA, uint32_t srcALen, const float32_t *pSrcB, uint32_t srcBLen, float32_t *pDst, uint32_t firstIndex, uint32_t numPoints)

```

riscv_status riscv_conv_partial_fast_opt_q15(const q15_t *pSrcA, uint32_t srcALen, const
                                             q15_t *pSrcB, uint32_t srcBLen, q15_t *pDst,
                                             uint32_t firstIndex, uint32_t numPoints, q15_t
                                             *pScratch1, q15_t *pScratch2)

                                      Points)

```

group **PartialConv**

Partial Convolution is equivalent to Convolution except that a subset of the output samples is generated. Each function has two additional arguments. *firstIndex* specifies the starting index of the subset of output samples. *numPoints* is the number of output samples to compute. The function computes the output in the range [*firstIndex*, ..., *firstIndex*+*numPoints*-1]. The output array *pDst* contains *numPoints* values.

The allowable range of output indices is [0 *srcALen*+*srcBLen*-2]. If the requested subset does not fall in this range then the functions return **RISCV_MATH_ARGUMENT_ERROR**. Otherwise the functions return **RISCV_MATH_SUCCESS**.

Note Refer to `riscv_conv_f32()` for details on fixed point behavior.

Fast Versions Fast versions are supported for Q31 and Q15 of partial convolution. Cycles for Fast versions are less compared to Q31 and Q15 of partial conv and the design requires the input signals should be scaled down to avoid intermediate overflows.

Opt Versions Opt versions are supported for Q15 and Q7. Design uses internal scratch buffer for getting good optimisation. These versions are optimised in cycles and consumes more memory (Scratch memory) compared to Q15 and Q7 versions of partial convolution

Functions

```

riscv_status riscv_conv_partial_f32(const float32_t *pSrcA, uint32_t srcALen, const
                                      float32_t *pSrcB, uint32_t srcBLen, float32_t *pDst,
                                      uint32_t firstIndex, uint32_t numPoints)

```

Partial convolution of floating-point sequences.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed

```
riscv_status riscv_conv_partial_fast_opt_q15(const q15_t *pSrcA, uint32_t srcALen,
                                             const q15_t *pSrcB, uint32_t srcBLen,
                                             q15_t *pDst, uint32_t firstIndex, uint32_t
                                             numPoints, q15_t *pScratch1, q15_t
                                             *pScratch2)
```

Partial convolution of Q15 sequences (fast version).

Partial convolution of Q15 sequences (fast version) for RISC-V Core with DSP enabled.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Remark Refer to riscv_conv_partial_q15() for a slower implementation of this function which uses a 64-bit accumulator to avoid wrap around distortion.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed
- [in] pScratch1: points to scratch buffer of size max(srcALen, srcBLen) + 2*min(srcALen, srcBLen) - 2
- [in] pScratch2: points to scratch buffer of size min(srcALen, srcBLen)

```
riscv_status riscv_conv_partial_fast_q15 (const q15_t *pSrcA, uint32_t srcALen, const
                                         q15_t *pSrcB, uint32_t srcBLen, q15_t *pDst,
                                         uint32_t firstIndex, uint32_t numPoints)
```

Partial convolution of Q15 sequences (fast version).

Partial convolution of Q15 sequences (fast version) for RISC-V Core with DSP enabled.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Remark Refer to riscv_conv_partial_q15() for a slower implementation of this function which uses a 64-bit accumulator to avoid wrap around distortion.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed

```
riscv_status riscv_conv_partial_fast_q31 (const q31_t *pSrcA, uint32_t srcALen, const
                                         q31_t *pSrcB, uint32_t srcBLen, q31_t *pDst,
                                         uint32_t firstIndex, uint32_t numPoints)
```

Partial convolution of Q31 sequences (fast version).

Partial convolution of Q31 sequences (fast version) for RISC-V Core with DSP enabled.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Remark Refer to riscv_conv_partial_q31() for a slower implementation of this function which uses a 64-bit accumulator to provide higher precision.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed

```
riscv_status riscv_conv_partial_opt_q15(const q15_t *pSrcA, uint32_t srcALen, const
                                         q15_t *pSrcB, uint32_t srcBLen, q15_t *pDst,
                                         uint32_t firstIndex, uint32_t numPoints, q15_t
                                         *pScratch1, q15_t *pScratch2)
```

Partial convolution of Q15 sequences.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Remark Refer to riscv_conv_partial_fast_q15() for a faster but less precise version of this function.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed
- [in] pScratch1: points to scratch buffer of size max(srcALen, srcBLen) + 2*min(srcALen, srcBLen) - 2.
- [in] pScratch2: points to scratch buffer of size min(srcALen, srcBLen).

```
riscv_status riscv_conv_partial_opt_q7(const q7_t *pSrcA, uint32_t srcALen, const q7_t
                                         *pSrcB, uint32_t srcBLen, q7_t *pDst, uint32_t firstIndex,
                                         uint32_t numPoints, q15_t *pScratch1, q15_t
                                         *pScratch2)
```

Partial convolution of Q7 sequences.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed

- [in] *pScratch1*: points to scratch buffer(of type *q15_t*) of size $\max(\text{srcALen}, \text{srcBLen}) + 2 \cdot \min(\text{srcALen}, \text{srcBLen}) - 2$.
- [in] *pScratch2*: points to scratch buffer (of type *q15_t*) of size $\min(\text{srcALen}, \text{srcBLen})$.

riscv_status **riscv_conv_partial_q15** (**const** *q15_t* **pSrcA*, uint32_t *srcALen*, **const** *q15_t* **pSrcB*, uint32_t *srcBLen*, *q15_t* **pDst*, uint32_t *firstIndex*, uint32_t *numPoints*)

Partial convolution of Q15 sequences.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 *srcALen*+*srcBLen*-2]

Remark Refer to *riscv_conv_partial_fast_q15()* for a faster but less precise version of this function.

Remark Refer to *riscv_conv_partial_opt_q15()* for a faster implementation of this function using scratch buffers.

Parameters

- [in] *pSrcA*: points to the first input sequence
- [in] *srcALen*: length of the first input sequence
- [in] *pSrcB*: points to the second input sequence
- [in] *srcBLen*: length of the second input sequence
- [out] *pDst*: points to the location where the output result is written
- [in] *firstIndex*: is the first output sample to start with
- [in] *numPoints*: is the number of output points to be computed

riscv_status **riscv_conv_partial_q31** (**const** *q31_t* **pSrcA*, uint32_t *srcALen*, **const** *q31_t* **pSrcB*, uint32_t *srcBLen*, *q31_t* **pDst*, uint32_t *firstIndex*, uint32_t *numPoints*)

Partial convolution of Q31 sequences.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 *srcALen*+*srcBLen*-2]

Remark Refer to *riscv_conv_partial_fast_q31()* for a faster but less precise implementation of this function.

Parameters

- [in] *pSrcA*: points to the first input sequence
- [in] *srcALen*: length of the first input sequence
- [in] *pSrcB*: points to the second input sequence
- [in] *srcBLen*: length of the second input sequence
- [out] *pDst*: points to the location where the output result is written
- [in] *firstIndex*: is the first output sample to start with

- [in] numPoints: is the number of output points to be computed

riscv_status **riscv_conv_partial_q7** (**const** q7_t *pSrcA, uint32_t srcALen, **const** q7_t *pSrcB, uint32_t srcBLen, q7_t *pDst, uint32_t firstIndex, uint32_t numPoints)

Partial convolution of Q7 sequences.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : requested subset is not in the range [0 srcALen+srcBLen-2]

Remark Refer to riscv_conv_partial_opt_q7() for a faster implementation of this function.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written
- [in] firstIndex: is the first output sample to start with
- [in] numPoints: is the number of output points to be computed

Correlation

void **riscv_correlate_f32** (**const** float32_t *pSrcA, uint32_t srcALen, **const** float32_t *pSrcB, uint32_t srcBLen, float32_t *pDst)

group Corr

Correlation is a mathematical operation that is similar to convolution. As with convolution, correlation uses two signals to produce a third signal. The underlying algorithms in correlation and convolution are identical except that one of the inputs is flipped in convolution. Correlation is commonly used to measure the similarity

between two signals. It has applications in pattern recognition, cryptanalysis, and searching. The NMSIS library provides correlation functions for Q7, Q15, Q31 and floating-point data types. Fast versions of the Q15 and Q31 functions are also provided.

Algorithm Let $a[n]$ and $b[n]$ be sequences of length `srcALen` and `srcBLen` samples respectively. The convolution of the two signals is denoted by In correlation, one of the signals is flipped in time

$$c[n] = \sum_{k=0}^{srcALen} a[k] b[k - n]$$

and this is mathematically defined as

The `pSrcA` points to the first input vector of length `srcALen` and `pSrcB` points to the second input vector of length `srcBLen`. The result $c[n]$ is of length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$ and is defined over the interval $n=0, 1, 2, \dots, (2 * \max(\text{srcALen}, \text{srcBLen}) - 2)$. The output result is written to `pDst` and the calling function must allocate $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$ words for the result.

Note The `pDst` should be initialized to all zeros before being used.

Fixed-Point Behavior Correlation requires summing up a large number of intermediate products. As such, the Q7, Q15, and Q31 functions run a risk of overflow and saturation. Refer to the function specific documentation below for further details of the particular algorithm used.

Fast Versions Fast versions are supported for Q31 and Q15. Cycles for Fast versions are less compared to Q31 and Q15 of correlate and the design requires the input signals should be scaled down to avoid intermediate overflows.

Opt Versions Opt versions are supported for Q15 and Q7. Design uses internal scratch buffer for getting good optimisation. These versions are optimised in cycles and consumes more memory (Scratch memory) compared to Q15 and Q7 versions of correlate

Functions

void **riscv_correlate_f32** (const float32_t *pSrcA, uint32_t srcALen, const float32_t *pSrcB, uint32_t srcBLen, float32_t *pDst)
Correlation of floating-point sequences.

Return none

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.

void **riscv_correlate_fast_opt_q15** (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB, uint32_t srcBLen, q15_t *pDst, q15_t *pScratch)
Correlation of Q15 sequences (fast version).

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. Scale down one of the inputs by $1/\min(\text{srcALen}, \text{srcBLen})$ to avoid overflow since a maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions is carried internally. The 2.30 accumulator is right shifted by 15 bits and then saturated to 1.15 format to yield the final result.

Remark Refer to `riscv_correlate_q15()` for a slower implementation of this function which uses a 64-bit accumulator to avoid wrap around distortion.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence.
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.
- [in] `pScratch`: points to scratch buffer of size $\max(\text{srcALen}, \text{srcBLen}) + 2 * \min(\text{srcALen}, \text{srcBLen}) - 2$.

```
void riscv_correlate_fast_q15 (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB,
                               uint32_t srcBLen, q15_t *pDst)
```

Correlation of Q15 sequences (fast version).

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. Scale down one of the inputs by $1/\min(\text{srcALen}, \text{srcBLen})$ to avoid overflow since a maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions is carried internally. The 2.30 accumulator is right shifted by 15 bits and then saturated to 1.15 format to yield the final result.

Remark Refer to `riscv_correlate_q15()` for a slower implementation of this function which uses a 64-bit accumulator to avoid wrap around distortion.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.

```
void riscv_correlate_fast_q31 (const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB,
                               uint32_t srcBLen, q31_t *pDst)
```

Correlation of Q31 sequences (fast version).

Return none

Scaling and Overflow Behavior This function is optimized for speed at the expense of fixed-point precision and overflow protection. The result of each 1.31 x 1.31 multiplication is truncated to 2.30 format. These intermediate results are accumulated in a 32-bit register in 2.30 format. Finally, the accumulator is saturated and converted to a 1.31 result.

The fast version has the same overflow behavior as the standard version but provides less precision since it discards the low 32 bits of each multiplication result. In order to avoid overflows completely the input signals must be scaled down. The input signals should be scaled down to avoid intermediate overflows. Scale down one of the inputs by $1/\min(\text{srcALen}, \text{srcBLen})$ to avoid overflows since a maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions is carried internally.

Remark Refer to `riscv_correlate_q31()` for a slower implementation of this function which uses 64-bit accumulation to provide higher precision.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.

```
void riscv_correlate_opt_q15 (const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB,  
                             uint32_t srcBLen, q15_t *pDst, q15_t *pScratch)
```

Correlation of Q15 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both inputs are in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. This approach provides 33 guard bits and there is no risk of overflow. The 34.30 result is then truncated to 34.15 format by discarding the low 15 bits and then saturated to 1.15 format.

Remark Refer to `riscv_correlate_fast_q15()` for a faster but less precise version of this function.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.
- [in] `pScratch`: points to scratch buffer of size $\max(\text{srcALen}, \text{srcBLen}) + 2 * \min(\text{srcALen}, \text{srcBLen}) - 2$.

```
void riscv_correlate_opt_q7 (const q7_t *pSrcA, uint32_t srcALen, const q7_t *pSrcB,  
                             uint32_t srcBLen, q7_t *pDst, q15_t *pScratch1, q15_t  
                             *pScratch2)
```

Correlation of Q7 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. Both the inputs are represented in 1.7 format and multiplications yield a 2.14 result. The 2.14 intermediate results are accumulated in a 32-bit accumulator in 18.14 format. This approach provides 17 guard bits and there is no risk of overflow as long as $\max(\text{srcALen}, \text{srcBLen}) < 131072$. The 18.14 result is then truncated to 18.7 format by discarding the low 7 bits and then saturated to 1.7 format.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.
- [in] pScratch1: points to scratch buffer (of type q15_t) of size $\max(\text{srcALen}, \text{srcBLen}) + 2 * \min(\text{srcALen}, \text{srcBLen}) - 2$.
- [in] pScratch2: points to scratch buffer (of type q15_t) of size $\min(\text{srcALen}, \text{srcBLen})$.

```
void riscv_correlate_q15(const q15_t *pSrcA, uint32_t srcALen, const q15_t *pSrcB,
                        uint32_t srcBLen, q15_t *pDst)
```

Correlation of Q15 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both inputs are in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. This approach provides 33 guard bits and there is no risk of overflow. The 34.30 result is then truncated to 34.15 format by discarding the low 15 bits and then saturated to 1.15 format.

Remark Refer to `riscv_correlate_fast_q15()` for a faster but less precise version of this function.

Remark Refer to `riscv_correlate_opt_q15()` for a faster implementation of this function using scratch buffers.

Parameters

- [in] pSrcA: points to the first input sequence
- [in] srcALen: length of the first input sequence
- [in] pSrcB: points to the second input sequence
- [in] srcBLen: length of the second input sequence
- [out] pDst: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.

```
void riscv_correlate_q31(const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB,
                        uint32_t srcBLen, q31_t *pDst)
```

Correlation of Q31 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. Scale down one of the inputs by $1/\min(\text{srcALen}, \text{srcBLen})$ to avoid overflows since a maximum of $\min(\text{srcALen}, \text{srcBLen})$ number of additions is carried internally. The 2.62 accumulator is right shifted by 31 bits and saturated to 1.31 format to yield the final result.

Remark Refer to `riscv_correlate_fast_q31()` for a faster but less precise implementation of this function.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.

```
void riscv_correlate_q7 (const q7_t *pSrcA, uint32_t srcALen, const q7_t *pSrcB, uint32_t  
                        srcBLen, q7_t *pDst)
```

Correlation of Q7 sequences.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. Both the inputs are represented in 1.7 format and multiplications yield a 2.14 result. The 2.14 intermediate results are accumulated in a 32-bit accumulator in 18.14 format. This approach provides 17 guard bits and there is no risk of overflow as long as $\max(\text{srcALen}, \text{srcBLen}) < 131072$. The 18.14 result is then truncated to 18.7 format by discarding the low 7 bits and saturated to 1.7 format.

Remark Refer to `riscv_correlate_opt_q7()` for a faster implementation of this function.

Parameters

- [in] `pSrcA`: points to the first input sequence
- [in] `srcALen`: length of the first input sequence
- [in] `pSrcB`: points to the second input sequence
- [in] `srcBLen`: length of the second input sequence
- [out] `pDst`: points to the location where the output result is written. Length $2 * \max(\text{srcALen}, \text{srcBLen}) - 1$.

Finite Impulse Response (FIR) Decimator

```

group **FIR_decimate**

These functions combine an FIR filter together with a decimator. They are used in multirate systems for reducing the sample rate of a signal without introducing aliasing distortion. Conceptually, the functions are equivalent to the block diagram below: When decimating by a factor of M, the signal should be prefiltered by a lowpass filter with a normalized cutoff frequency of $1/M$ in order to prevent aliasing distortion. The user of the function is responsible for providing the filter

coefficients.

The FIR decimator functions provided in the NMSIS DSP Library combine the FIR filter and the decimator in an efficient manner. Instead of calculating all of the FIR filter outputs and discarding $M-1$ out of every M , only the samples output by the decimator are computed. The functions operate on blocks of input and output data. `pSrc` points to an array of `blockSize` input values and `pDst` points to an array of `blockSize/M` output values. In order to have an integer number of output samples `blockSize` must always be a multiple of the decimation factor M .

The library provides separate functions for Q15, Q31 and floating-point data types.

Algorithm: The FIR portion of the algorithm uses the standard form filter: where, $b[n]$ are the filter coefficients.

The `pCoeffs` points to a coefficient array of size `numTaps`. Coefficients are stored in time reversed order.

`pState` points to a state array of size `numTaps + blockSize - 1`. Samples in the state buffer are stored in the order:

The state variables are updated after each block of data is processed, the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable array should be allocated separately. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer.
- Checks to make sure that the size of the input is a multiple of the decimation factor. To do this manually without calling the init function, assign the follow subfields of the instance structure: numTaps, pCoeffs, M (decimation factor), pState. Also set all of the values in pState to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. The code below statically initializes each of the 3 different data type filter instance structures where M is the decimation factor; numTaps is the number of filter coefficients in the filter; pCoeffs is the address of the coefficient buffer; pState is the address of the state buffer. Be sure to set the values in the state buffer to zeros when doing static initialization.

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the FIR decimate filter functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

void **riscv_fir_decimate_f32** (**const** riscv_fir_decimate_instance_f32 *S, **const** float32_t *pSrc, float32_t *pDst, uint32_t blockSize)
Processing function for floating-point FIR decimator.

Return none

Parameters

- [in] S: points to an instance of the floating-point FIR decimator structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

void **riscv_fir_decimate_fast_q15** (**const** riscv_fir_decimate_instance_q15 *S, **const** q15_t *pSrc, q15_t *pDst, uint32_t blockSize)
Processing function for the Q15 FIR decimator (fast variant).

Processing function for the Q15 FIR decimator (fast variant) for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around and distorts the result. In order to avoid overflows completely the input signal must be scaled down by log2(numTaps) bits (log2 is read as log to the base 2). The 2.30 accumulator is then truncated to 2.15 format and saturated to yield the 1.15 result.

Remark Refer to riscv_fir_decimate_q15() for a slower implementation of this function which uses 64-bit accumulation to avoid wrap around distortion. Both the slow and the fast versions use the same instance structure. Use function riscv_fir_decimate_init_q15() to initialize the filter structure.

Parameters

- [in] S: points to an instance of the Q15 FIR decimator structure
- [in] pSrc: points to the block of input data

- [out] pDst: points to the block of output data
- [in] blockSize: number of input samples to process per call

void **riscv_fir_decimate_fast_q31** (const riscv_fir_decimate_instance_q31 *S, const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)

Processing function for the Q31 FIR decimator (fast variant).

Processing function for the Q31 FIR decimator (fast variant) for RISC-V Core with DSP enabled.

Return none

Scaling and Overflow Behavior This function is optimized for speed at the expense of fixed-point precision and overflow protection. The result of each 1.31 x 1.31 multiplication is truncated to 2.30 format. These intermediate results are added to a 2.30 accumulator. Finally, the accumulator is saturated and converted to a 1.31 result. The fast version has the same overflow behavior as the standard version and provides less precision since it discards the low 32 bits of each multiplication result. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits (where \log_2 is read as log to the base 2).

Remark Refer to riscv_fir_decimate_q31() for a slower implementation of this function which uses a 64-bit accumulator to provide higher precision. Both the slow and the fast versions use the same instance structure. Use function riscv_fir_decimate_init_q31() to initialize the filter structure.

Parameters

- [in] S: points to an instance of the Q31 FIR decimator structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

riscv_status **riscv_fir_decimate_init_f32** (riscv_fir_decimate_instance_f32 *S, uint16_t numTaps, uint8_t M, const float32_t *pCoeffs, float32_t *pState, uint32_t blockSize)

Initialization function for the floating-point FIR decimator.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_LENGTH_ERROR : blockSize is not a multiple of M

Details pCoeffs points to the array of filter coefficients stored in time reversed order:

pState points to the array of state variables. pState is of length numTaps+blockSize-1 words where blockSize is the number of input samples passed to riscv_fir_decimate_f32(). M is the decimation factor.

Parameters

- [inout] S: points to an instance of the floating-point FIR decimator structure
- [in] numTaps: number of coefficients in the filter
- [in] M: decimation factor
- [in] pCoeffs: points to the filter coefficients
- [in] pState: points to the state buffer
- [in] blockSize: number of input samples to process per call

```
riscv_status riscv_fir_decimate_init_q15 (riscv_fir_decimate_instance_q15 *S, uint16_t num-  
Taps, uint8_t M, const q15_t *pCoeffs, q15_t  
*pState, uint32_t blockSize)
```

Initialization function for the Q15 FIR decimator.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_LENGTH_ERROR : blockSize is not a multiple of M

Details pCoeffs points to the array of filter coefficients stored in time reversed order:

pState points to the array of state variables. pState is of length numTaps+blockSize-1 words where blockSize is the number of input samples to the call riscv_fir_decimate_q15(). M is the decimation factor.

Parameters

- [inout] S: points to an instance of the Q15 FIR decimator structure
- [in] numTaps: number of coefficients in the filter
- [in] M: decimation factor
- [in] pCoeffs: points to the filter coefficients
- [in] pState: points to the state buffer
- [in] blockSize: number of input samples to process

```
riscv_status riscv_fir_decimate_init_q31 (riscv_fir_decimate_instance_q31 *S, uint16_t num-  
Taps, uint8_t M, const q31_t *pCoeffs, q31_t  
*pState, uint32_t blockSize)
```

Initialization function for the Q31 FIR decimator.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_LENGTH_ERROR : blockSize is not a multiple of M

Details pCoeffs points to the array of filter coefficients stored in time reversed order:

pState points to the array of state variables. pState is of length numTaps+blockSize-1 words where blockSize is the number of input samples passed to riscv_fir_decimate_q31(). M is the decimation factor.

Parameters

- [inout] S: points to an instance of the Q31 FIR decimator structure
- [in] numTaps: number of coefficients in the filter
- [in] M: decimation factor
- [in] pCoeffs: points to the filter coefficients
- [in] pState: points to the state buffer
- [in] blockSize: number of input samples to process

```
void riscv_fir_decimate_q15 (const riscv_fir_decimate_instance_q15 *S, const q15_t *pSrc,  
q15_t *pDst, uint32_t blockSize)
```

Processing function for the Q15 FIR decimator.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

Remark Refer to `riscv_fir_decimate_fast_q15()` for a faster but less precise implementation of this function.

Parameters

- [in] `S`: points to an instance of the Q15 FIR decimator structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of input samples to process per call

```
void riscv_fir_decimate_q31 (const riscv_fir_decimate_instance_q31 *S, const q31_t *pSrc,
                             q31_t *pDst, uint32_t blockSize)
```

Processing function for the Q31 FIR decimator.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits (where \log_2 is read as log to the base 2). After all multiply-accumulates are performed, the 2.62 accumulator is truncated to 1.32 format and then saturated to 1.31 format.

Remark Refer to `riscv_fir_decimate_fast_q31()` for a faster but less precise implementation of this function.

Parameters

- [in] `S`: points to an instance of the Q31 FIR decimator structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process

Finite Impulse Response (FIR) Filters

```

group FIR

This set of functions implements Finite Impulse Response (FIR) filters for Q7, Q15, Q31, and floating-point data types. Fast versions of Q15 and Q31 are also provided. The functions operate on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` and `pDst` points to input and output arrays containing `blockSize` values.

The array length L must be a multiple of x . $L = x * a$:

- x is 4 for f32
- x is 4 for q31
- x is 4 for f16 (so managed like the f32 version and not like the q15 one)
- x is 8 for q15
- x is 16 for q7

Algorithm The FIR filter algorithm is based upon a sequence of multiply-accumulate (MAC) operations. Each filter coefficient $b[n]$ is multiplied by a state variable which equals a previous input sample $x[n]$.

`pCoeffs` points to a coefficient array of size `numTaps`. Coefficients are stored in time reversed order.

`pState` points to a state array of size `numTaps + blockSize - 1`. Samples in the state buffer are stored in the following order.

Note that the length of the state buffer exceeds the length of the coefficient array by `blockSize-1`. The increased state buffer length allows circular addressing, which is traditionally used in the FIR filters, to be

avoided and yields a significant speed improvement. The state variables are updated after each block of data is processed; the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable arrays cannot be shared. There are separate instance structure declarations for each of the 4 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numTaps`, `pCoeffs`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros before static initialization. The code below statically initializes each of the 4 different data type filter instance structures where `numTaps` is the number of filter coefficients in the filter; `pState` is the address of the state buffer; `pCoeffs` is the address of the coefficient buffer.

Initialization of Helium version For Helium version the array of coefficients must be padded with zero to contain a full number of lanes.

The additional coefficients ($x * a - \text{numTaps}$) must be set to 0. `numTaps` is still set to its right value in the init function. It means that the implementation may require to read more coefficients due to the vectorization and to avoid having to manage too many different cases in the code.

Helium state buffer The state buffer must contain some additional temporary data used during the computation but which is not the state of the FIR. The first `A` samples are temporary data. The remaining samples are the state of the FIR filter.

So the state buffer has size `numTaps + A + blockSize - 1` :

- `A` is `blockSize` for f32
- `A` is $8 * \text{ceil}(\text{blockSize}/8)$ for f16
- `A` is $8 * \text{ceil}(\text{blockSize}/4)$ for q31
- `A` is 0 for other datatypes (q15 and q7)

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the FIR filter functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

```
void riscv_fir_f32 (const riscv_fir_instance_f32 *S, const float32_t *pSrc, float32_t *pDst,
                   uint32_t blockSize)
```

Processing function for floating-point FIR filter.

Processing function for the floating-point FIR filter.

Return none

Parameters

- [in] *S*: points to an instance of the floating-point FIR filter structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

void **riscv_fir_fast_q15**(const riscv_fir_instance_q15 **S*, const q15_t **pSrc*, q15_t **pDst*,
uint32_t *blockSize*)

Processing function for the Q15 FIR filter (fast version).

Processing function for the fast Q15 FIR filter (fast version).

Return none

Scaling and Overflow Behavior This fast version uses a 32-bit accumulator with 2.30 format. The accumulator maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around and distorts the result. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits. The 2.30 accumulator is then truncated to 2.15 format and saturated to yield the 1.15 result.

Remark Refer to `riscv_fir_q15()` for a slower implementation of this function which uses 64-bit accumulation to avoid wrap around distortion. Both the slow and the fast versions use the same instance structure. Use function `riscv_fir_init_q15()` to initialize the filter structure.

Parameters

- [in] *S*: points to an instance of the Q15 FIR filter structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

IAR_ONLY_LOW_OPTIMIZATION_ENTER void **riscv_fir_fast_q31**(const riscv_fir_instance_q31

Processing function for the Q31 FIR filter (fast version).

Processing function for the fast Q31 FIR filter (fast version).

Return none

Scaling and Overflow Behavior This function is optimized for speed at the expense of fixed-point precision and overflow protection. The result of each 1.31 x 1.31 multiplication is truncated to 2.30 format. These intermediate results are added to a 2.30 accumulator. Finally, the accumulator is saturated and converted to a 1.31 result. The fast version has the same overflow behavior as the standard version and provides less precision since it discards the low 32 bits of each multiplication result. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits.

Remark Refer to `riscv_fir_q31()` for a slower implementation of this function which uses a 64-bit accumulator to provide higher precision. Both the slow and the fast versions use the same instance structure. Use function `riscv_fir_init_q31()` to initialize the filter structure.

Parameters

- [in] *S*: points to an instance of the Q31 structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

void **riscv_fir_init_f32** (riscv_fir_instance_f32 *S, uint16_t numTaps, const float32_t *pCoeffs, float32_t *pState, uint32_t blockSize)

Initialization function for the floating-point FIR filter.

Return none

Details pCoeffs points to the array of filter coefficients stored in time reversed order:

pState points to the array of state variables and some working memory for the Helium version. pState is of length numTaps+blockSize-1 samples (except for Helium - see below), where blockSize is the number of input samples processed by each call to riscv_fir_f32().

Initialization of Helium version For Helium version the array of coefficients must be a multiple of 4 (4a) even if less than 4a coefficients are defined in the FIR. The additional coefficients (4a - numTaps) must be set to 0. numTaps is still set to its right value in the init function. It means that the implementation may require to read more coefficients due to the vectorization and to avoid having to manage too many different cases in the code.

Helium state buffer The state buffer must contain some additional temporary data used during the computation but which is not the state of the FIR. The first blockSize samples are temporary data. The remaining samples are the state of the FIR filter. So the state buffer has size numTaps + 2 * blockSize - 1

Parameters

- [inout] S: points to an instance of the floating-point FIR filter structure
- [in] numTaps: number of filter coefficients in the filter
- [in] pCoeffs: points to the filter coefficients buffer
- [in] pState: points to the state buffer
- [in] blockSize: number of samples processed per call

riscv_status **riscv_fir_init_q15** (riscv_fir_instance_q15 *S, uint16_t numTaps, const q15_t *pCoeffs, q15_t *pState, uint32_t blockSize)

Initialization function for the Q15 FIR filter.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : numTaps is not greater than or equal to 4 and even

Details pCoeffs points to the array of filter coefficients stored in time reversed order: Note that numTaps must be even and greater than or equal to 4. To implement an odd length filter simply increase numTaps by 1 and set the last coefficient to zero. For example, to implement a filter with numTaps=3 and coefficients set numTaps=4 and use the coefficients: Similarly, to implement a two point filter set numTaps=4 and use the coefficients: pState points to the array of state variables. pState is of length numTaps+blockSize, when running on RISC-V Core with DSP enabled and is of length numTaps+blockSize-1, when running on RISC-V Core without DSP where blockSize is the number of input samples processed by each call to riscv_fir_q15().

Initialization of Helium version For Helium version the array of coefficients must be a multiple of 8 (8a) even if less than 8a coefficients are defined in the FIR. The additional coefficients (8a - numTaps) must be set to 0. numTaps is still set to its right value in the init function. It means that the implementation may require to read more coefficients due to the vectorization and to avoid having to manage too many different cases in the code.

Parameters

- [inout] *S*: points to an instance of the Q15 FIR filter structure.
- [in] *numTaps*: number of filter coefficients in the filter. Must be even and greater than or equal to 4.
- [in] *pCoeffs*: points to the filter coefficients buffer.
- [in] *pState*: points to the state buffer.
- [in] *blockSize*: number of samples processed per call.

```
void riscv_fir_init_q31 (riscv_fir_instance_q31 *S, uint16_t numTaps, const q31_t *pCoeffs,  
                        q31_t *pState, uint32_t blockSize)
```

Initialization function for the Q31 FIR filter.

Return none

Details *pCoeffs* points to the array of filter coefficients stored in time reversed order: *pState* points to the array of state variables. *pState* is of length *numTaps*+*blockSize*-1 samples (except for Helium - see below), where *blockSize* is the number of input samples processed by each call to `riscv_fir_q31()`.

Initialization of Helium version For Helium version the array of coefficients must be a multiple of 4 (4a) even if less than 4a coefficients are defined in the FIR. The additional coefficients (4a - *numTaps*) must be set to 0. *numTaps* is still set to its right value in the init function. It means that the implementation may require to read more coefficients due to the vectorization and to avoid having to manage too many different cases in the code.

Helium state buffer The state buffer must contain some additional temporary data used during the computation but which is not the state of the FIR. The first $2 \times 4 \times \text{ceil}(\text{blockSize}/4)$ samples are temporary data. The remaining samples are the state of the FIR filter. So the state buffer has size $\text{numTaps} + 8 \times \text{ceil}(\text{blockSize}/4) + \text{blockSize} - 1$

Parameters

- [inout] *S*: points to an instance of the Q31 FIR filter structure
- [in] *numTaps*: number of filter coefficients in the filter
- [in] *pCoeffs*: points to the filter coefficients buffer
- [in] *pState*: points to the state buffer
- [in] *blockSize*: number of samples processed

```
void riscv_fir_init_q7 (riscv_fir_instance_q7 *S, uint16_t numTaps, const q7_t *pCoeffs, q7_t  
                        *pState, uint32_t blockSize)
```

Initialization function for the Q7 FIR filter.

Return none

Details *pCoeffs* points to the array of filter coefficients stored in time reversed order:

pState points to the array of state variables. *pState* is of length *numTaps*+*blockSize*-1 samples, where *blockSize* is the number of input samples processed by each call to `riscv_fir_q7()`.

Initialization of Helium version For Helium version the array of coefficients must be a multiple of 16 (16a) even if less than 16a coefficients are defined in the FIR. The additional coefficients (16a - *numTaps*) must be set to 0. *numTaps* is still set to its right value in the init function. It means that the implementation may require to read more coefficients due to the vectorization and to avoid having to manage too many different cases in the code.

Parameters

- [inout] *S*: points to an instance of the Q7 FIR filter structure
- [in] *numTaps*: number of filter coefficients in the filter
- [in] *pCoeffs*: points to the filter coefficients buffer
- [in] *pState*: points to the state buffer
- [in] *blockSize*: number of samples processed

void **riscv_fir_q15**(**const** riscv_fir_instance_q15 **S*, **const** q15_t **pSrc*, q15_t **pDst*, uint32_t *blockSize*)

Processing function for the Q15 FIR filter.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

Remark Refer to `riscv_fir_fast_q15()` for a faster but less precise implementation of this function.

Parameters

- [in] *S*: points to an instance of the Q15 FIR filter structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

void **riscv_fir_q31**(**const** riscv_fir_instance_q31 **S*, **const** q31_t **pSrc*, q31_t **pDst*, uint32_t *blockSize*)

Processing function for Q31 FIR filter.

Processing function for the Q31 FIR filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits. After all multiply-accumulates are performed, the 2.62 accumulator is right shifted by 31 bits and saturated to 1.31 format to yield the final result.

Remark Refer to `riscv_fir_fast_q31()` for a faster but less precise implementation of this filter.

Parameters

- [in] *S*: points to an instance of the Q31 FIR filter structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

```
void riscv_fir_q7 (const riscv_fir_instance_q7 *S, const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)
```

Processing function for Q7 FIR filter.

Processing function for the Q7 FIR filter.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. Both coefficients and state variables are represented in 1.7 format and multiplications yield a 2.14 result. The 2.14 intermediate results are accumulated in a 32-bit accumulator in 18.14 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. The accumulator is converted to 18.7 format by discarding the low 7 bits. Finally, the result is truncated to 1.7 format.

Parameters

- [in] S: points to an instance of the Q7 FIR filter structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

Finite Impulse Response (FIR) Lattice Filters

```
void riscv_fir_lattice_f32 (const riscv_fir_lattice_instance_f32 *S, const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)
```

```
void riscv_fir_lattice_init_f32 (riscv_fir_lattice_instance_f32 *S, uint16_t numStages, const float32_t *pCoeffs, float32_t *pState)
```

```
void riscv_fir_lattice_init_q15 (riscv_fir_lattice_instance_q15 *S, uint16_t numStages, const q15_t *pCoeffs, q15_t *pState)
```

```
void riscv_fir_lattice_init_q31 (riscv_fir_lattice_instance_q31 *S, uint16_t numStages, const q31_t *pCoeffs, q31_t *pState)
```

```
void riscv_fir_lattice_q15 (const riscv_fir_lattice_instance_q15 *S, const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)
```

```
void riscv_fir_lattice_q31 (const riscv_fir_lattice_instance_q31 *S, const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
```

group **FIR_Lattice**

This set of functions implements Finite Impulse Response (FIR) lattice filters for Q15, Q31 and floating-point data types. Lattice filters are used in a variety of adaptive filter applications. The filter structure is feedforward and the net impulse response is finite length. The functions operate on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` and `pDst` point to input and output arrays containing `blockSize` values.

Algorithm

The following difference equation is implemented:

`pCoeffs` points to the array of reflection coefficients of size `numStages`. Reflection Coefficients are stored in the following order.

where `M` is number of stages

`pState` points to a state array of size `numStages`. The state variables (`g` values) hold previous inputs and are stored in the following order. The state variables are updated after each block of data is processed; the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable arrays cannot be shared. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numStages`, `pCoeffs`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros and then manually initialize the instance structure as follows:

where `numStages` is the number of stages in the filter; `pState` is the address of the state buffer; `pCoeffs` is the address of the coefficient buffer.

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the FIR Lattice filter functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

```
void riscv_fir_lattice_f32 (const riscv_fir_lattice_instance_f32 *S, const float32_t *pSrc,
                           float32_t *pDst, uint32_t blockSize)
```

Processing function for the floating-point FIR lattice filter.

Return none

Parameters

- [in] `S`: points to an instance of the floating-point FIR lattice structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data

- [in] blockSize: number of samples to process

void **riscv_fir_lattice_init_f32** (riscv_fir_lattice_instance_f32 *S, uint16_t numStages, **const** float32_t *pCoeffs, float32_t *pState)

Initialization function for the floating-point FIR lattice filter.

Return none

Parameters

- [in] S: points to an instance of the floating-point FIR lattice structure
- [in] numStages: number of filter stages
- [in] pCoeffs: points to the coefficient buffer. The array is of length numStages
- [in] pState: points to the state buffer. The array is of length numStages

void **riscv_fir_lattice_init_q15** (riscv_fir_lattice_instance_q15 *S, uint16_t numStages, **const** q15_t *pCoeffs, q15_t *pState)

Initialization function for the Q15 FIR lattice filter.

Return none

Parameters

- [in] S: points to an instance of the Q15 FIR lattice structure
- [in] numStages: number of filter stages
- [in] pCoeffs: points to the coefficient buffer. The array is of length numStages
- [in] pState: points to the state buffer. The array is of length numStages

void **riscv_fir_lattice_init_q31** (riscv_fir_lattice_instance_q31 *S, uint16_t numStages, **const** q31_t *pCoeffs, q31_t *pState)

Initialization function for the Q31 FIR lattice filter.

Return none

Parameters

- [in] S: points to an instance of the Q31 FIR lattice structure
- [in] numStages: number of filter stages
- [in] pCoeffs: points to the coefficient buffer. The array is of length numStages
- [in] pState: points to the state buffer. The array is of length numStages

void **riscv_fir_lattice_q15** (**const** riscv_fir_lattice_instance_q15 *S, **const** q15_t *pSrc, q15_t *pDst, uint32_t blockSize)

Processing function for Q15 FIR lattice filter.

Processing function for the Q15 FIR lattice filter.

Return none

Parameters

- [in] S: points to an instance of the Q15 FIR lattice structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data

- [in] `blockSize`: number of samples to process

```
void riscv_fir_lattice_q31 (const riscv_fir_lattice_instance_q31 *S, const q31_t *pSrc,
                           q31_t *pDst, uint32_t blockSize)
```

Processing function for the Q31 FIR lattice filter.

Return none

Scaling and Overflow Behavior In order to avoid overflows the input signal must be scaled down by $2^{\log_2(\text{numStages})}$ bits.

Parameters

- [in] `S`: points to an instance of the Q31 FIR lattice structure
- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `blockSize`: number of samples to process

Finite Impulse Response (FIR) Sparse Filters

```
void riscv_fir_sparse_f32 (riscv_fir_sparse_instance_f32 *S, const float32_t *pSrc, float32_t *pDst,
                           float32_t *pScratchIn, uint32_t blockSize)
```

```
void riscv_fir_sparse_init_f32 (riscv_fir_sparse_instance_f32 *S, uint16_t numTaps, const
                                float32_t *pCoeffs, float32_t *pState, int32_t *pTapDelay, uint16_t
                                maxDelay, uint32_t blockSize)
```

```
void riscv_fir_sparse_init_q15 (riscv_fir_sparse_instance_q15 *S, uint16_t numTaps, const q15_t
                                *pCoeffs, q15_t *pState, int32_t *pTapDelay, uint16_t maxDelay,
                                uint32_t blockSize)
```

```
void riscv_fir_sparse_init_q31 (riscv_fir_sparse_instance_q31 *S, uint16_t numTaps, const q31_t
                                *pCoeffs, q31_t *pState, int32_t *pTapDelay, uint16_t maxDelay,
                                uint32_t blockSize)
```

```
void riscv_fir_sparse_init_q7 (riscv_fir_sparse_instance_q7 *S, uint16_t numTaps, const q7_t
                                *pCoeffs, q7_t *pState, int32_t *pTapDelay, uint16_t maxDelay,
                                uint32_t blockSize)
```

```
void riscv_fir_sparse_q15 (riscv_fir_sparse_instance_q15 *S, const q15_t *pSrc, q15_t *pDst, q15_t
                            *pScratchIn, q31_t *pScratchOut, uint32_t blockSize)
```

```
void riscv_fir_sparse_q31 (riscv_fir_sparse_instance_q31 *S, const q31_t *pSrc, q31_t *pDst, q31_t
                            *pScratchIn, uint32_t blockSize)
```

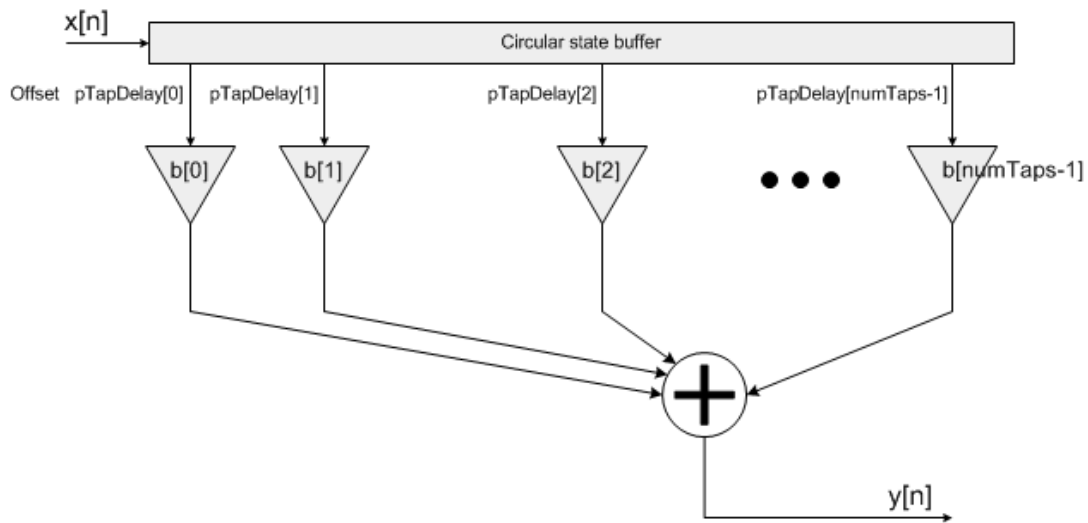

```
void riscv_fir_sparse_q7 (riscv_fir_sparse_instance_q7 *S, const q7_t *pSrc, q7_t *pDst, q7_t
                           *pScratchIn, q31_t *pScratchOut, uint32_t blockSize)
```

group **FIR_Sparse**

This group of functions implements sparse FIR filters. Sparse FIR filters are equivalent to standard FIR filters except that most of the coefficients are equal to zero. Sparse filters are used for simulating reflections in communications and audio applications.

There are separate functions for Q7, Q15, Q31, and floating-point data types. The functions operate on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` and `pDst` points to input and output arrays respectively containing `blockSize` values.

Algorithm The sparse filter instant structure contains an array of tap indices `pTapDelay` which specifies the locations of the non-zero coefficients. This is in addition to the coefficient array `b`. The implementation essentially skips the multiplications by zero and leads to an efficient realization.

`pCoeffs` points to a coefficient array of size `numTaps`; `pTapDelay` points to an array of nonzero indices and is also of size `numTaps`; `pState` points to a state array of size `maxDelay + blockSize`, where `maxDelay` is the largest offset value that is ever used in the `pTapDelay` array. Some of the processing functions also require temporary working buffers.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient and offset arrays may be shared among several instances while state variable arrays cannot be shared. There are separate instance structure declarations for each of the 4 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numTaps`, `pCoeffs`, `pTapDelay`, `maxDelay`, `stateIndex`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros before static initialization. The code below statically initializes each of the 4 different data type filter instance structures

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the sparse FIR filter functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

```
void riscv_fir_sparse_f32 (riscv_fir_sparse_instance_f32 *S, const float32_t *pSrc, float32_t
                          *pDst, float32_t *pScratchIn, uint32_t blockSize)
Processing function for the floating-point sparse FIR filter.
```

Return none

Parameters

- `[in] S`: points to an instance of the floating-point sparse FIR structure

- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `pScratchIn`: points to a temporary buffer of size `blockSize`
- [in] `blockSize`: number of input samples to process

void **riscv_fir_sparse_init_f32** (riscv_fir_sparse_instance_f32 *S, uint16_t *numTaps*, const float32_t **pCoeffs*, float32_t **pState*, int32_t **pTapDelay*, uint16_t *maxDelay*, uint32_t *blockSize*)

Initialization function for the floating-point sparse FIR filter.

Return none

Details `pCoeffs` holds the filter coefficients and has length `numTaps`. `pState` holds the filter's state variables and must be of length `maxDelay + blockSize`, where `maxDelay` is the maximum number of delay line values. `blockSize` is the number of samples processed by the `riscv_fir_sparse_f32()` function.

Parameters

- [inout] `S`: points to an instance of the floating-point sparse FIR structure
- [in] `numTaps`: number of nonzero coefficients in the filter
- [in] `pCoeffs`: points to the array of filter coefficients
- [in] `pState`: points to the state buffer
- [in] `pTapDelay`: points to the array of offset times
- [in] `maxDelay`: maximum offset time supported
- [in] `blockSize`: number of samples that will be processed per block

void **riscv_fir_sparse_init_q15** (riscv_fir_sparse_instance_q15 *S, uint16_t *numTaps*, const q15_t **pCoeffs*, q15_t **pState*, int32_t **pTapDelay*, uint16_t *maxDelay*, uint32_t *blockSize*)

Initialization function for the Q15 sparse FIR filter.

Return none

Details `pCoeffs` holds the filter coefficients and has length `numTaps`. `pState` holds the filter's state variables and must be of length `maxDelay + blockSize`, where `maxDelay` is the maximum number of delay line values. `blockSize` is the number of words processed by `riscv_fir_sparse_q15()` function.

Parameters

- [inout] `S`: points to an instance of the Q15 sparse FIR structure
- [in] `numTaps`: number of nonzero coefficients in the filter
- [in] `pCoeffs`: points to the array of filter coefficients
- [in] `pState`: points to the state buffer
- [in] `pTapDelay`: points to the array of offset times
- [in] `maxDelay`: maximum offset time supported
- [in] `blockSize`: number of samples that will be processed per block

```
void riscv_fir_sparse_init_q31 (riscv_fir_sparse_instance_q31 *S, uint16_t numTaps, const
                               q31_t *pCoeffs, q31_t *pState, int32_t *pTapDelay, uint16_t
                               maxDelay, uint32_t blockSize)
```

Initialization function for the Q31 sparse FIR filter.

Return none

Details *pCoeffs* holds the filter coefficients and has length *numTaps*. *pState* holds the filter's state variables and must be of length *maxDelay* + *blockSize*, where *maxDelay* is the maximum number of delay line values. *blockSize* is the number of words processed by *riscv_fir_sparse_q31()* function.

Parameters

- [inout] *S*: points to an instance of the Q31 sparse FIR structure
- [in] *numTaps*: number of nonzero coefficients in the filter
- [in] *pCoeffs*: points to the array of filter coefficients
- [in] *pState*: points to the state buffer
- [in] *pTapDelay*: points to the array of offset times
- [in] *maxDelay*: maximum offset time supported
- [in] *blockSize*: number of samples that will be processed per block

```
void riscv_fir_sparse_init_q7 (riscv_fir_sparse_instance_q7 *S, uint16_t numTaps, const
                               q7_t *pCoeffs, q7_t *pState, int32_t *pTapDelay, uint16_t
                               maxDelay, uint32_t blockSize)
```

Initialization function for the Q7 sparse FIR filter.

Return none

Details *pCoeffs* holds the filter coefficients and has length *numTaps*. *pState* holds the filter's state variables and must be of length *maxDelay* + *blockSize*, where *maxDelay* is the maximum number of delay line values. *blockSize* is the number of samples processed by the *riscv_fir_sparse_q7()* function.

Parameters

- [inout] *S*: points to an instance of the Q7 sparse FIR structure
- [in] *numTaps*: number of nonzero coefficients in the filter
- [in] *pCoeffs*: points to the array of filter coefficients
- [in] *pState*: points to the state buffer
- [in] *pTapDelay*: points to the array of offset times
- [in] *maxDelay*: maximum offset time supported
- [in] *blockSize*: number of samples that will be processed per block

```
void riscv_fir_sparse_q15 (riscv_fir_sparse_instance_q15 *S, const q15_t *pSrc, q15_t *pDst,
                           q15_t *pScratchIn, q31_t *pScratchOut, uint32_t blockSize)
```

Processing function for the Q15 sparse FIR filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 32-bit accumulator. The 1.15×1.15 multiplications yield a 2.30 result and these are added to a 2.30 accumulator. Thus the full precision of the multiplications is maintained but there is only a single guard bit in the accumulator. If the accumulator result overflows it will wrap around rather than saturate. After all multiply-accumulates are performed, the 2.30 accumulator is truncated to 2.15 format and then saturated to 1.15 format. In order to avoid overflows the input signal or coefficients must be scaled down by $\log_2(\text{numTaps})$ bits.

Parameters

- [in] *S*: points to an instance of the Q15 sparse FIR structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *pScratchIn*: points to a temporary buffer of size *blockSize*
- [in] *pScratchOut*: points to a temporary buffer of size *blockSize*
- [in] *blockSize*: number of input samples to process per call

```
void riscv_fir_sparse_q31 (riscv_fir_sparse_instance_q31 *S, const q31_t *pSrc, q31_t *pDst,
                          q31_t *pScratchIn, uint32_t blockSize)
```

Processing function for the Q31 sparse FIR filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 32-bit accumulator. The 1.31×1.31 multiplications are truncated to 2.30 format. This leads to loss of precision on the intermediate multiplications and provides only a single guard bit. If the accumulator result overflows, it wraps around rather than saturate. In order to avoid overflows the input signal or coefficients must be scaled down by $\log_2(\text{numTaps})$ bits.

Parameters

- [in] *S*: points to an instance of the Q31 sparse FIR structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *pScratchIn*: points to a temporary buffer of size *blockSize*
- [in] *blockSize*: number of input samples to process

```
void riscv_fir_sparse_q7 (riscv_fir_sparse_instance_q7 *S, const q7_t *pSrc, q7_t *pDst, q7_t
                          *pScratchIn, q31_t *pScratchOut, uint32_t blockSize)
```

Processing function for the Q7 sparse FIR filter.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. Both coefficients and state variables are represented in 1.7 format and multiplications yield a 2.14 result. The 2.14 intermediate results are accumulated in a 32-bit accumulator in 18.14 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. The accumulator is then converted to 18.7 format by discarding the low 7 bits. Finally, the result is truncated to 1.7 format.

Parameters

- [in] *S*: points to an instance of the Q7 sparse FIR structure

- [in] `pSrc`: points to the block of input data
- [out] `pDst`: points to the block of output data
- [in] `pScratchIn`: points to a temporary buffer of size `blockSize`
- [in] `pScratchOut`: points to a temporary buffer of size `blockSize`
- [in] `blockSize`: number of input samples to process

Infinite Impulse Response (IIR) Lattice Filters

```
void riscv_iir_lattice_f32 (const riscv_iir_lattice_instance_f32 *S, const float32_t *pSrc,
                           float32_t *pDst, uint32_t blockSize)
```

```
void riscv_iir_lattice_init_f32 (riscv_iir_lattice_instance_f32 *S, uint16_t numStages, float32_t
                                *pkCoeffs, float32_t *pvCoeffs, float32_t *pState, uint32_t block-
                                Size)
```

```
void riscv_iir_lattice_init_q15 (riscv_iir_lattice_instance_q15 *S, uint16_t numStages, q15_t
                                *pkCoeffs, q15_t *pvCoeffs, q15_t *pState, uint32_t blockSize)
```

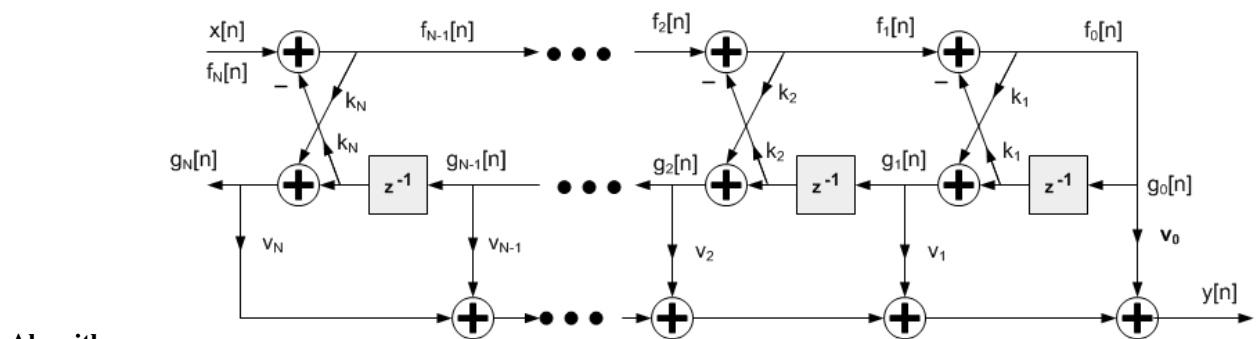

```
void riscv_iir_lattice_init_q31 (riscv_iir_lattice_instance_q31 *S, uint16_t numStages, q31_t
                                *pkCoeffs, q31_t *pvCoeffs, q31_t *pState, uint32_t blockSize)
```

```
void riscv_iir_lattice_q15 (const riscv_iir_lattice_instance_q15 *S, const q15_t *pSrc, q15_t
                             *pDst, uint32_t blockSize)
```

```
void riscv_iir_lattice_q31 (const riscv_iir_lattice_instance_q31 *S, const q31_t *pSrc, q31_t
                             *pDst, uint32_t blockSize)
```

group IIR_Lattice

This set of functions implements lattice filters for Q15, Q31 and floating-point data types. Lattice filters are used in a variety of adaptive filter applications. The filter structure has feedforward and feedback components and the net impulse response is infinite length. The functions operate on blocks of input and output data and each call to the function processes `blockSize` samples through the filter. `pSrc` and `pDst` point to input and output arrays containing `blockSize` values.

`pkCoeffs` points to array of reflection coefficients of size `numStages`. Reflection Coefficients are stored in time-reversed order.

`pvCoeffs` points to the array of ladder coefficients of size `(numStages+1)`. Ladder coefficients are stored in time-reversed order.

`pState` points to a state array of size `numStages + blockSize`. The state variables shown in the figure above (the `g` values) are stored in the `pState` array. The state variables are updated after each block of data is processed; the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable arrays cannot be shared. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numStages`, `pkCoeffs`, `pvCoeffs`, `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros and then manually initialize the instance structure as follows:

where `numStages` is the number of stages in the filter; `pState` points to the state buffer array; `pkCoeffs` points to array of the reflection coefficients; `pvCoeffs` points to the array of ladder coefficients.

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the IIR lattice filter functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

void **riscv_iir_lattice_f32** (const riscv_iir_lattice_instance_f32 *S, const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

Processing function for the floating-point IIR lattice filter.

Return none

Parameters

- [in] S: points to an instance of the floating-point IIR lattice structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

void **riscv_iir_lattice_init_f32** (riscv_iir_lattice_instance_f32 *S, uint16_t numStages, float32_t *pkCoeffs, float32_t *pvCoeffs, float32_t *pState, uint32_t blockSize)

Initialization function for the floating-point IIR lattice filter.

Return none

Parameters

- [in] S: points to an instance of the floating-point IIR lattice structure
- [in] numStages: number of stages in the filter
- [in] pkCoeffs: points to reflection coefficient buffer. The array is of length `numStages`

- [in] `pvCoeffs`: points to ladder coefficient buffer. The array is of length `numStages+1`
- [in] `pState`: points to state buffer. The array is of length `numStages+blockSize`
- [in] `blockSize`: number of samples to process

void **riscv_iir_lattice_init_q15** (riscv_iir_lattice_instance_q15 **S*, uint16_t *numStages*, q15_t **pkCoeffs*, q15_t **pvCoeffs*, q15_t **pState*, uint32_t *blockSize*)

Initialization function for the Q15 IIR lattice filter.

Return none

Parameters

- [in] *S*: points to an instance of the Q15 IIR lattice structure
- [in] *numStages*: number of stages in the filter
- [in] *pkCoeffs*: points to reflection coefficient buffer. The array is of length `numStages`
- [in] *pvCoeffs*: points to ladder coefficient buffer. The array is of length `numStages+1`
- [in] *pState*: points to state buffer. The array is of length `numStages+blockSize`
- [in] *blockSize*: number of samples to process

void **riscv_iir_lattice_init_q31** (riscv_iir_lattice_instance_q31 **S*, uint16_t *numStages*, q31_t **pkCoeffs*, q31_t **pvCoeffs*, q31_t **pState*, uint32_t *blockSize*)

Initialization function for the Q31 IIR lattice filter.

Return none

Parameters

- [in] *S*: points to an instance of the Q31 IIR lattice structure
- [in] *numStages*: number of stages in the filter
- [in] *pkCoeffs*: points to reflection coefficient buffer. The array is of length `numStages`
- [in] *pvCoeffs*: points to ladder coefficient buffer. The array is of length `numStages+1`
- [in] *pState*: points to state buffer. The array is of length `numStages+blockSize`
- [in] *blockSize*: number of samples to process

void **riscv_iir_lattice_q15** (const riscv_iir_lattice_instance_q15 **S*, const q15_t **pSrc*, q15_t **pDst*, uint32_t *blockSize*)

Processing function for the Q15 IIR lattice filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

Parameters

- [in] *S*: points to an instance of the Q15 IIR lattice structure

- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

void **riscv_iir_lattice_q31**(const riscv_iir_lattice_instance_q31 *S, const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
Processing function for the Q31 IIR lattice filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by $2 \cdot \log_2(\text{numStages})$ bits. After all multiply-accumulates are performed, the 2.62 accumulator is saturated to 1.32 format and then truncated to 1.31 format.

Parameters

- [in] S: points to an instance of the Q31 IIR lattice structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

Least Mean Square (LMS) Filters

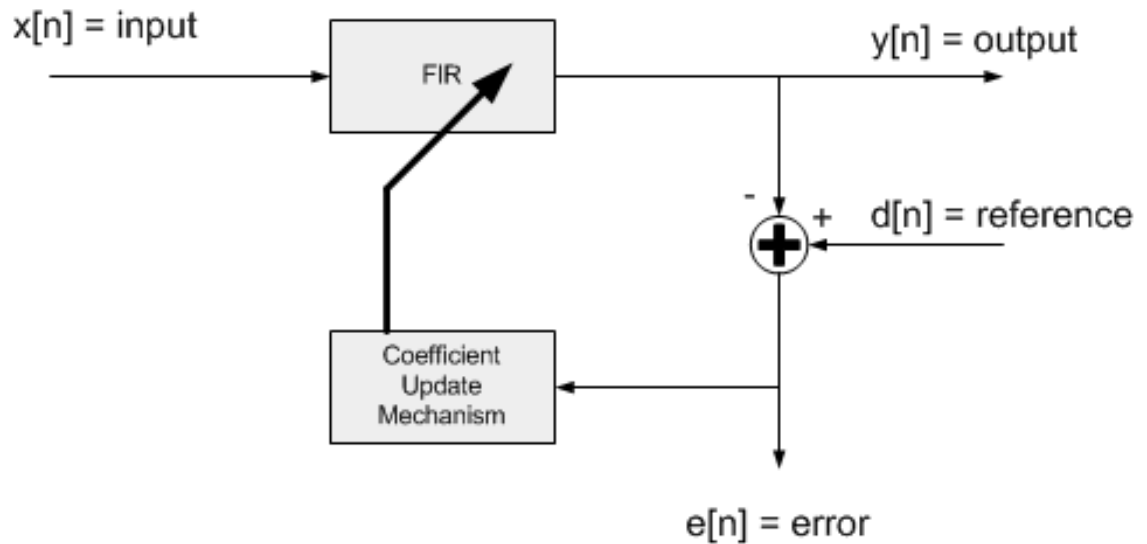

void **riscv_lms_f32**(const riscv_lms_instance_f32 *S, const float32_t *pSrc, float32_t *pRef, float32_t *pOut, float32_t *pErr, uint32_t blockSize)
void **riscv_lms_init_f32**(riscv_lms_instance_f32 *S, uint16_t numTaps, float32_t *pCoeffs, float32_t *pState, float32_t mu, uint32_t blockSize)
void **riscv_lms_init_q15**(riscv_lms_instance_q15 *S, uint16_t numTaps, q15_t *pCoeffs, q15_t *pState, q15_t mu, uint32_t blockSize, uint32_t postShift)
void **riscv_lms_init_q31**(riscv_lms_instance_q31 *S, uint16_t numTaps, q31_t *pCoeffs, q31_t *pState, q31_t mu, uint32_t blockSize, uint32_t postShift)

void **riscv_lms_q31**(const riscv_lms_instance_q31 *S, const q31_t *pSrc, q31_t *pRef, q31_t *pOut, q31_t *pErr, uint32_t blockSize)

group LMS

LMS filters are a class of adaptive filters that are able to “learn” an unknown transfer functions. LMS filters use a gradient descent method in which the filter coefficients are updated based on the instantaneous error signal. Adaptive filters are often used in communication systems, equalizers, and noise removal. The NMSIS DSP Library contains LMS filter functions that operate on Q15, Q31, and floating-point data types. The library also contains normalized LMS filters in which the filter coefficient adaptation is independent of the level of the input signal.

An LMS filter consists of two components as shown below. The first component is a standard transversal or FIR filter. The second component is a coefficient update mechanism. The LMS filter has two input signals. The “input” feeds the FIR filter while the “reference input” corresponds to the desired output of the FIR filter. That is, the FIR filter coefficients are updated so that the output of the FIR filter matches the reference input. The filter coefficient update mechanism is based on the difference

between the FIR filter output and the reference input. This “error signal” tends towards zero as the filter adapts. The LMS processing functions accept the input and reference input signals and generate the filter output and error signal. The functions operate on blocks of data and each call to the function processes `blockSize` samples through the filter. `pSrc` points to input signal, `pRef` points to reference signal, `pOut` points to output signal and `pErr` points to error signal. All arrays contain `blockSize`

values.

The functions operate on a block-by-block basis. Internally, the filter coefficients $b[n]$ are updated on a sample-by-sample basis. The convergence of the LMS filter is slower compared to the normalized LMS algorithm.

Algorithm The output signal $y[n]$ is computed by a standard FIR filter:

The error signal equals the difference between the reference signal $d[n]$ and the filter output:

After each sample of the error signal is computed, the filter coefficients $b[k]$ are updated on a sample-by-sample basis: where μ is the step size and controls the rate of coefficient convergence.

In the APIs, `pCoeffs` points to a coefficient array of size `numTaps`. Coefficients are stored in time reversed order.

`pState` points to a state array of size `numTaps + blockSize - 1`. Samples in the state buffer are stored in the order:

Note that the length of the state buffer exceeds the length of the coefficient array by `blockSize-1` samples. The increased state buffer length allows circular addressing, which is traditionally used in FIR filters, to be avoided and yields a significant speed improvement. The state variables are updated after each block of data is processed.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter and coefficient and state arrays cannot be shared among instances. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.

- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: numTaps, pCoeffs, mu, postShift (not for f32), pState. Also set all of the values in pState to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Set the values in the state buffer to zeros before static initialization. The code below statically initializes each of the 3 different data type filter instance structures where numTaps is the number of filter coefficients in the filter; pState is the address of the state buffer; pCoeffs is the address of the coefficient buffer; mu is the step size parameter; and postShift is the shift applied to coefficients.

Fixed-Point Behavior Care must be taken when using the Q15 and Q31 versions of the LMS filter. The following issues must be considered:

- Scaling of coefficients
- Overflow and saturation

Scaling of Coefficients Filter coefficients are represented as fractional values and coefficients are restricted to lie in the range $[-1 \ +1]$. The fixed-point functions have an additional scaling parameter postShift. At the output of the filter's accumulator is a shift register which shifts the result by postShift bits. This essentially scales the filter coefficients by $2^{\text{postShift}}$ and allows the filter coefficients to exceed the range $[+1 \ -1]$. The value of postShift is set by the user based on the expected gain through the system being modeled.

Overflow and Saturation Overflow and saturation behavior of the fixed-point Q15 and Q31 versions are described separately as part of the function specific documentation below.

Functions

void **riscv_lms_f32** (const riscv_lms_instance_f32 *S, const float32_t *pSrc, float32_t *pRef, float32_t *pOut, float32_t *pErr, uint32_t blockSize)
Processing function for floating-point LMS filter.

Return none

Parameters

- [in] S: points to an instance of the floating-point LMS filter structure
- [in] pSrc: points to the block of input data
- [in] pRef: points to the block of reference data
- [out] pOut: points to the block of output data
- [out] pErr: points to the block of error data
- [in] blockSize: number of samples to process

void **riscv_lms_init_f32** (riscv_lms_instance_f32 *S, uint16_t numTaps, float32_t *pCoeffs, float32_t *pState, float32_t mu, uint32_t blockSize)
Initialization function for floating-point LMS filter.

Return none

Details pCoeffs points to the array of filter coefficients stored in time reversed order: The initial filter coefficients serve as a starting point for the adaptive filter. pState points to an array of length numTaps+blockSize-1 samples, where blockSize is the number of input samples processed by each call to riscv_lms_f32().

Parameters

- [in] *S*: points to an instance of the floating-point LMS filter structure
- [in] *numTaps*: number of filter coefficients
- [in] *pCoeffs*: points to coefficient buffer
- [in] *pState*: points to state buffer
- [in] *mu*: step size that controls filter coefficient updates
- [in] *blockSize*: number of samples to process

void **riscv_lms_init_q15** (riscv_lms_instance_q15 **S*, uint16_t *numTaps*, q15_t **pCoeffs*, q15_t **pState*, q15_t *mu*, uint32_t *blockSize*, uint32_t *postShift*)

Initialization function for the Q15 LMS filter.

Return none

Details *pCoeffs* points to the array of filter coefficients stored in time reversed order: The initial filter coefficients serve as a starting point for the adaptive filter. *pState* points to the array of state variables and size of array is *numTaps*+*blockSize*-1 samples, where *blockSize* is the number of input samples processed by each call to `riscv_lms_q15()`.

Parameters

- [in] *S*: points to an instance of the Q15 LMS filter structure.
- [in] *numTaps*: number of filter coefficients.
- [in] *pCoeffs*: points to coefficient buffer.
- [in] *pState*: points to state buffer.
- [in] *mu*: step size that controls filter coefficient updates.
- [in] *blockSize*: number of samples to process.
- [in] *postShift*: bit shift applied to coefficients.

void **riscv_lms_init_q31** (riscv_lms_instance_q31 **S*, uint16_t *numTaps*, q31_t **pCoeffs*, q31_t **pState*, q31_t *mu*, uint32_t *blockSize*, uint32_t *postShift*)

Initialization function for Q31 LMS filter.

Return none

Details *pCoeffs* points to the array of filter coefficients stored in time reversed order: The initial filter coefficients serve as a starting point for the adaptive filter. *pState* points to an array of length *numTaps*+*blockSize*-1 samples, where *blockSize* is the number of input samples processed by each call to `riscv_lms_q31()`.

Parameters

- [in] *S*: points to an instance of the Q31 LMS filter structure
- [in] *numTaps*: number of filter coefficients
- [in] *pCoeffs*: points to coefficient buffer
- [in] *pState*: points to state buffer
- [in] *mu*: step size that controls filter coefficient updates
- [in] *blockSize*: number of samples to process

- [in] `postShift`: bit shift applied to coefficients

```
void riscv_lms_q15(const riscv_lms_instance_q15 *S, const q15_t *pSrc, q15_t *pRef, q15_t
                  *pOut, q15_t *pErr, uint32_t blockSize)
```

Processing function for Q15 LMS filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

In this filter, filter coefficients are updated for each sample and the updation of filter coefficients are saturated.

Parameters

- [in] `S`: points to an instance of the Q15 LMS filter structure
- [in] `pSrc`: points to the block of input data
- [in] `pRef`: points to the block of reference data
- [out] `pOut`: points to the block of output data
- [out] `pErr`: points to the block of error data
- [in] `blockSize`: number of samples to process

```
void riscv_lms_q31(const riscv_lms_instance_q31 *S, const q31_t *pSrc, q31_t *pRef, q31_t
                  *pOut, q31_t *pErr, uint32_t blockSize)
```

Processing function for Q31 LMS filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clips. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits. The reference signal should not be scaled down. After all multiply-accumulates are performed, the 2.62 accumulator is shifted and saturated to 1.31 format to yield the final result. The output signal and error signal are in 1.31 format.

In this filter, filter coefficients are updated for each sample and the updation of filter coefficients are saturated.

Parameters

- [in] `S`: points to an instance of the Q31 LMS filter structure.
- [in] `pSrc`: points to the block of input data.
- [in] `pRef`: points to the block of reference data.
- [out] `pOut`: points to the block of output data.
- [out] `pErr`: points to the block of error data.
- [in] `blockSize`: number of samples to process.

Normalized LMS Filters

```

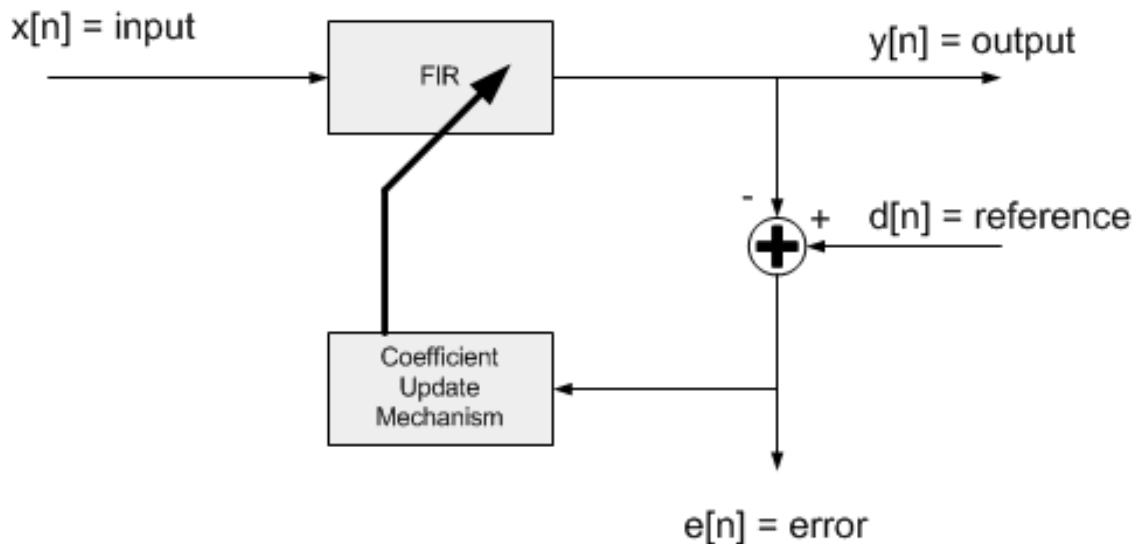

void riscv_lms_norm_f32 (riscv_lms_norm_instance_f32 *S, const float32_t *pSrc, float32_t *pRef,
                        float32_t *pOut, float32_t *pErr, uint32_t blockSize)
void riscv_lms_norm_init_f32 (riscv_lms_norm_instance_f32 *S, uint16_t numTaps, float32_t *pCo-
                        effs, float32_t *pState, float32_t mu, uint32_t blockSize)
void riscv_lms_norm_init_q15 (riscv_lms_norm_instance_q15 *S, uint16_t numTaps, q15_t *pCoeffs,
                        q15_t *pState, q15_t mu, uint32_t blockSize, uint8_t postShift)
void riscv_lms_norm_init_q31 (riscv_lms_norm_instance_q31 *S, uint16_t numTaps, q31_t *pCoeffs,
                        q31_t *pState, q31_t mu, uint32_t blockSize, uint8_t postShift)
void riscv_lms_norm_q15 (riscv_lms_norm_instance_q15 *S, const q15_t *pSrc, q15_t *pRef, q15_t
                        *pOut, q15_t *pErr, uint32_t blockSize)
void riscv_lms_norm_q31 (riscv_lms_norm_instance_q31 *S, const q31_t *pSrc, q31_t *pRef, q31_t
                        *pOut, q31_t *pErr, uint32_t blockSize)

```

group **LMS_NORM**

This set of functions implements a commonly used adaptive filter. It is related to the Least Mean Square (LMS) adaptive filter and includes an additional normalization factor which increases the adaptation rate of the filter. The NMSIS DSP Library contains normalized LMS filter functions that operate on Q15, Q31, and floating-point data types.

A normalized least mean square (NLMS) filter consists of two components as shown below. The first component is a standard transversal or FIR filter. The second component is a coefficient update mechanism. The NLMS filter has two input signals. The “input” feeds the FIR filter while the “reference input” corresponds to the desired output of the FIR filter. That is, the FIR filter coefficients are updated so that the output of the FIR filter matches the reference input. The filter coefficient update mechanism is based on the difference between the FIR filter output and the reference input. This “error signal” tends towards zero as the filter adapts. The NLMS processing functions accept the input and reference input signals and generate the filter output and error signal. The functions operate on blocks of data and each call to the function processes `blockSize` samples through the filter. `pSrc` points to input signal, `pRef` points to reference signal, `pOut` points to output signal and `pErr` points to error signal. All arrays contain `blockSize`

values.

The functions operate on a block-by-block basis. Internally, the filter coefficients $b[n]$ are updated on a sample-by-sample basis. The convergence of the LMS filter is slower compared to the normalized LMS algorithm.

Algorithm The output signal $y[n]$ is computed by a standard FIR filter:

The error signal equals the difference between the reference signal $d[n]$ and the filter output:

After each sample of the error signal is computed the instantaneous energy of the filter state variables is calculated: The filter coefficients $b[k]$ are then updated on a sample-by-sample basis: where μ is the step size and controls the rate of coefficient convergence.

In the APIs, `pCoeffs` points to a coefficient array of size `numTaps`. Coefficients are stored in time reversed order.

`pState` points to a state array of size `numTaps + blockSize - 1`. Samples in the state buffer are stored in the order:

Note that the length of the state buffer exceeds the length of the coefficient array by `blockSize-1` samples. The increased state buffer length allows circular addressing, which is traditionally used in FIR filters, to be avoided and yields a significant speed improvement. The state variables are updated after each block of data is processed.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter and coefficient and state arrays cannot be shared among instances. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer. To do this manually without calling the init function, assign the follow subfields of the instance structure: `numTaps`, `pCoeffs`, `mu`, `energy`, `x0`, `pState`. Also set all of the values in `pState` to zero. For Q7, Q15, and Q31 the following fields must also be initialized; `recipTable`, `postShift`

Instance structure cannot be placed into a const data section and it is recommended to use the initialization function.

Fixed-Point Behavior Care must be taken when using the Q15 and Q31 versions of the normalised LMS filter. The following issues must be considered:

- Scaling of coefficients
- Overflow and saturation

Scaling of Coefficients (fixed point versions) Filter coefficients are represented as fractional values and coefficients are restricted to lie in the range $[-1 \ +1)$. The fixed-point functions have an additional scaling parameter `postShift`. At the output of the filter's accumulator is a shift register which shifts the result by `postShift` bits. This essentially scales the filter coefficients by $2^{\text{postShift}}$ and allows the filter coefficients to exceed the range $[-1 \ +1)$. The value of `postShift` is set by the user based on the expected gain through the system being modeled.

Overflow and Saturation (fixed point versions) Overflow and saturation behavior of the fixed-point Q15 and Q31 versions are described separately as part of the function specific documentation below.

Functions

void **riscv_lms_norm_f32** (riscv_lms_norm_instance_f32 *S, **const** float32_t *pSrc, float32_t *pRef, float32_t *pOut, float32_t *pErr, uint32_t blockSize)
Processing function for floating-point normalized LMS filter.

Return none

Parameters

- [in] S: points to an instance of the floating-point normalized LMS filter structure
- [in] pSrc: points to the block of input data
- [in] pRef: points to the block of reference data
- [out] pOut: points to the block of output data
- [out] pErr: points to the block of error data
- [in] blockSize: number of samples to process

void **riscv_lms_norm_init_f32** (riscv_lms_norm_instance_f32 *S, uint16_t numTaps, float32_t *pCoeffs, float32_t *pState, float32_t mu, uint32_t blockSize)
Initialization function for floating-point normalized LMS filter.

Return none

Details pCoeffs points to the array of filter coefficients stored in time reversed order: The initial filter coefficients serve as a starting point for the adaptive filter. pState points to an array of length numTaps+blockSize-1 samples, where blockSize is the number of input samples processed by each call to riscv_lms_norm_f32().

Parameters

- [in] S: points to an instance of the floating-point LMS filter structure
- [in] numTaps: number of filter coefficients
- [in] pCoeffs: points to coefficient buffer
- [in] pState: points to state buffer
- [in] mu: step size that controls filter coefficient updates
- [in] blockSize: number of samples to process

void **riscv_lms_norm_init_q15** (riscv_lms_norm_instance_q15 *S, uint16_t numTaps, q15_t *pCoeffs, q15_t *pState, q15_t mu, uint32_t blockSize, uint8_t postShift)
Initialization function for Q15 normalized LMS filter.

Return none

Details pCoeffs points to the array of filter coefficients stored in time reversed order: The initial filter coefficients serve as a starting point for the adaptive filter. pState points to the array of state variables and size of array is numTaps+blockSize-1 samples, where blockSize is the number of input samples processed by each call to riscv_lms_norm_q15().

Parameters

- [in] S: points to an instance of the Q15 normalized LMS filter structure.
- [in] numTaps: number of filter coefficients.

- [in] `pCoeffs`: points to coefficient buffer.
- [in] `pState`: points to state buffer.
- [in] `mu`: step size that controls filter coefficient updates.
- [in] `blockSize`: number of samples to process.
- [in] `postShift`: bit shift applied to coefficients.

```
void riscv_lms_norm_init_q31(riscv_lms_norm_instance_q31 *S, uint16_t numTaps, q31_t
                           *pCoeffs, q31_t *pState, q31_t mu, uint32_t blockSize, uint8_t
                           postShift)
```

Initialization function for Q31 normalized LMS filter.

Return none

Details `pCoeffs` points to the array of filter coefficients stored in time reversed order: The initial filter coefficients serve as a starting point for the adaptive filter. `pState` points to an array of length `numTaps+blockSize-1` samples, where `blockSize` is the number of input samples processed by each call to `riscv_lms_norm_q31()`.

Parameters

- [in] `S`: points to an instance of the Q31 normalized LMS filter structure.
- [in] `numTaps`: number of filter coefficients.
- [in] `pCoeffs`: points to coefficient buffer.
- [in] `pState`: points to state buffer.
- [in] `mu`: step size that controls filter coefficient updates.
- [in] `blockSize`: number of samples to process.
- [in] `postShift`: bit shift applied to coefficients.

```
void riscv_lms_norm_q15(riscv_lms_norm_instance_q15 *S, const q15_t *pSrc, q15_t *pRef,
                       q15_t *pOut, q15_t *pErr, uint32_t blockSize)
```

Processing function for Q15 normalized LMS filter.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

In this filter, filter coefficients are updated for each sample and the updation of filter coefficients are saturated.

Parameters

- [in] `S`: points to an instance of the Q15 normalized LMS filter structure
- [in] `pSrc`: points to the block of input data
- [in] `pRef`: points to the block of reference data
- [out] `pOut`: points to the block of output data
- [out] `pErr`: points to the block of error data

- [in] blockSize: number of samples to process

```
void riscv_lms_norm_q31 (riscv_lms_norm_instance_q31 *S, const q31_t *pSrc, q31_t *pRef,  
                        q31_t *pOut, q31_t *pErr, uint32_t blockSize)
```

Processing function for Q31 normalized LMS filter.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{numTaps})$ bits. The reference signal should not be scaled down. After all multiply-accumulates are performed, the 2.62 accumulator is shifted and saturated to 1.31 format to yield the final result. The output signal and error signal are in 1.31 format.

In this filter, filter coefficients are updated for each sample and the updation of filter coefficients are saturated.

Parameters

- [in] S: points to an instance of the Q31 normalized LMS filter structure
- [in] pSrc: points to the block of input data
- [in] pRef: points to the block of reference data
- [out] pOut: points to the block of output data
- [out] pErr: points to the block of error data
- [in] blockSize: number of samples to process

Finite Impulse Response (FIR) Interpolator

```
void riscv_fir_interpolate_f32 (const riscv_fir_interpolate_instance_f32 *S, const float32_t  
                               *pSrc, float32_t *pDst, uint32_t blockSize)
```

```
riscv_status riscv_fir_interpolate_init_f32 (riscv_fir_interpolate_instance_f32 *S, uint8_t L,  
                                              uint16_t numTaps, const float32_t *pCoeffs,  
                                              float32_t *pState, uint32_t blockSize)
```

```
riscv_status riscv_fir_interpolate_init_q15 (riscv_fir_interpolate_instance_q15 *S, uint8_t L,  
                                              uint16_t numTaps, const q15_t *pCoeffs, q15_t  
                                              *pState, uint32_t blockSize)
```

```
riscv_status riscv_fir_interpolate_init_q31 (riscv_fir_interpolate_instance_q31 *S, uint8_t L,  
                                              uint16_t numTaps, const q31_t *pCoeffs, q31_t  
                                              *pState, uint32_t blockSize)
```

```
void riscv_fir_interpolate_q15 (const riscv_fir_interpolate_instance_q15 *S, const q15_t  
                               *pSrc, q15_t *pDst, uint32_t blockSize)
```

```
void riscv_fir_interpolate_q31 (const riscv_fir_interpolate_instance_q31 *S, const q31_t  
                               *pSrc, q31_t *pDst, uint32_t blockSize)
```

group **FIR_Interpolate**

These functions combine an upsampler (zero stuffer) and an FIR filter. They are used in multirate systems for increasing the sample rate of a signal without introducing high frequency images. Conceptually, the functions are equivalent to the block diagram below: After upsampling by a factor of L , the signal should be filtered by a lowpass filter with a normalized cutoff frequency of $1/L$ in order to elimi-

nate high frequency copies of the spectrum. The user of the function is responsible for providing the filter

coefficients.

The FIR interpolator functions provided in the NMSIS DSP Library combine the upsampler and FIR filter in an efficient manner. The upsampler inserts $L-1$ zeros between each sample. Instead of multiplying by these zero values, the FIR filter is designed to skip them. This leads to an efficient implementation without any wasted effort. The functions operate on blocks of input and output data. `pSrc` points to an array of `blockSize` input values and `pDst` points to an array of `blockSize*L` output values.

The library provides separate functions for Q15, Q31, and floating-point data types.

Algorithm The functions use a polyphase filter structure: This approach is more efficient than straightforward upsample-then-filter algorithms. With this method the computation is reduced by a factor of $1/L$ when compared to using a standard FIR filter.

`pCoeffs` points to a coefficient array of size `numTaps`. `numTaps` must be a multiple of the interpolation factor L and this is checked by the initialization functions. Internally, the function divides the FIR filter's impulse response into shorter filters of length `phaseLength=numTaps/L`. Coefficients are stored in time reversed order.

`pState` points to a state array of size `blockSize + phaseLength - 1`. Samples in the state buffer are stored in the order:

The state variables are updated after each block of data is processed, the coefficients are untouched.

Instance Structure The coefficients and state variables for a filter are stored together in an instance data structure. A separate instance structure must be defined for each filter. Coefficient arrays may be shared among several instances while state variable array should be allocated separately. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Zeros out the values in the state buffer.
- Checks to make sure that the length of the filter is a multiple of the interpolation factor. To do this manually without calling the init function, assign the follow subfields of the instance structure: `L` (interpolation factor), `pCoeffs`, `phaseLength` (`numTaps / L`), `pState`. Also set all of the values in `pState` to zero.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. The code below statically initializes each of the 3 different data type filter instance structures

where L is the interpolation factor; `phaseLength=numTaps/L` is the length of each of the shorter FIR filters used internally, `pCoeffs` is the address of the coefficient buffer; `pState` is the address of the state buffer. Be sure to set the values in the state buffer to zeros when doing static initialization.

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the FIR interpolate filter functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

void **riscv_fir_interpolate_f32** (**const** riscv_fir_interpolate_instance_f32 *S, **const** float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

Processing function for floating-point FIR interpolator.

Processing function for the floating-point FIR interpolator.

Return none

Parameters

- [in] S: points to an instance of the floating-point FIR interpolator structure
- [in] pSrc: points to the block of input data
- [out] pDst: points to the block of output data
- [in] blockSize: number of samples to process

riscv_status **riscv_fir_interpolate_init_f32** (riscv_fir_interpolate_instance_f32 *S, uint8_t L, uint16_t numTaps, **const** float32_t *pCoeffs, float32_t *pState, uint32_t blockSize)

Initialization function for the floating-point FIR interpolator.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : filter length numTaps is not a multiple of the interpolation factor L

Details pCoeffs points to the array of filter coefficients stored in time reversed order:

The length of the filter numTaps must be a multiple of the interpolation factor L.

pState points to the array of state variables. pState is of length (numTaps/L)+blockSize-1 words where blockSize is the number of input samples processed by each call to riscv_fir_interpolate_f32().

Parameters

- [inout] S: points to an instance of the floating-point FIR interpolator structure
- [in] L: upsample factor
- [in] numTaps: number of filter coefficients in the filter
- [in] pCoeffs: points to the filter coefficient buffer
- [in] pState: points to the state buffer
- [in] blockSize: number of input samples to process per call

riscv_status **riscv_fir_interpolate_init_q15** (riscv_fir_interpolate_instance_q15 *S, uint8_t L, uint16_t numTaps, **const** q15_t *pCoeffs, q15_t *pState, uint32_t blockSize)

Initialization function for the Q15 FIR interpolator.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful

- **RISCV_MATH_ARGUMENT_ERROR** : filter length `numTaps` is not a multiple of the interpolation factor `L`

Details `pCoeffs` points to the array of filter coefficients stored in time reversed order: The length of the filter `numTaps` must be a multiple of the interpolation factor `L`.

`pState` points to the array of state variables. `pState` is of length $(\text{numTaps}/L) + \text{blockSize} - 1$ words where `blockSize` is the number of input samples processed by each call to `riscv_fir_interpolate_q15()`.

Parameters

- `[inout]` `S`: points to an instance of the Q15 FIR interpolator structure
- `[in]` `L`: upsample factor
- `[in]` `numTaps`: number of filter coefficients in the filter
- `[in]` `pCoeffs`: points to the filter coefficient buffer
- `[in]` `pState`: points to the state buffer
- `[in]` `blockSize`: number of input samples to process per call

`riscv_status` **riscv_fir_interpolate_init_q31** (`riscv_fir_interpolate_instance_q31` *`S`, `uint8_t` `L`, `uint16_t` `numTaps`, **const** `q31_t` *`pCoeffs`, `q31_t` *`pState`, `uint32_t` `blockSize`)

Initialization function for the Q31 FIR interpolator.

Return execution status

- **RISCV_MATH_SUCCESS** : Operation successful
- **RISCV_MATH_ARGUMENT_ERROR** : filter length `numTaps` is not a multiple of the interpolation factor `L`

Details `pCoeffs` points to the array of filter coefficients stored in time reversed order: The length of the filter `numTaps` must be a multiple of the interpolation factor `L`.

`pState` points to the array of state variables. `pState` is of length $(\text{numTaps}/L) + \text{blockSize} - 1$ words where `blockSize` is the number of input samples processed by each call to `riscv_fir_interpolate_q31()`.

Parameters

- `[inout]` `S`: points to an instance of the Q31 FIR interpolator structure
- `[in]` `L`: upsample factor
- `[in]` `numTaps`: number of filter coefficients in the filter
- `[in]` `pCoeffs`: points to the filter coefficient buffer
- `[in]` `pState`: points to the state buffer
- `[in]` `blockSize`: number of input samples to process per call

`void` **riscv_fir_interpolate_q15** (**const** `riscv_fir_interpolate_instance_q15` *`S`, **const** `q15_t` *`pSrc`, `q15_t` *`pDst`, `uint32_t` `blockSize`)

Processing function for the Q15 FIR interpolator.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both coefficients and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

Parameters

- [in] *S*: points to an instance of the Q15 FIR interpolator structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

```
void riscv_fir_interpolate_q31 (const riscv_fir_interpolate_instance_q31 *S, const q31_t
                               *pSrc, q31_t *pDst, uint32_t blockSize)
```

Processing function for the Q31 FIR interpolator.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by $1/(\text{numTaps}/L)$. since $\text{numTaps}/L$ additions occur per output sample. After all multiply-accumulates are performed, the 2.62 accumulator is truncated to 1.32 format and then saturated to 1.31 format.

Parameters

- [in] *S*: points to an instance of the Q31 FIR interpolator structure
- [in] *pSrc*: points to the block of input data
- [out] *pDst*: points to the block of output data
- [in] *blockSize*: number of samples to process

group **groupFilters**

3.3.5 Matrix Functions

Matrix Addition

```
riscv_status riscv_mat_add_f32 (const riscv_matrix_instance_f32 *pSrcA, const
                                riscv_matrix_instance_f32 *pSrcB, riscv_matrix_instance_f32 *pDst)
```

```
riscv_status riscv_mat_add_q15 (const riscv_matrix_instance_q15 *pSrcA, const
                                riscv_matrix_instance_q15 *pSrcB, riscv_matrix_instance_q15 *pDst)
```

```
riscv_status riscv_mat_add_q31 (const riscv_matrix_instance_q31 *pSrcA, const
                                riscv_matrix_instance_q31 *pSrcB, riscv_matrix_instance_q31 *pDst)
```

group **MatrixAdd**

Adds two matrices. The functions check to make sure that *pSrcA*,

$pSrcB$, and $pDst$ have the same number of rows and columns.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix} = \begin{bmatrix} a_{11}+b_{11} & a_{12}+b_{12} & a_{13}+b_{13} \\ a_{21}+b_{21} & a_{22}+b_{22} & a_{23}+b_{23} \\ a_{31}+b_{31} & a_{32}+b_{32} & a_{33}+b_{33} \end{bmatrix}$$

Functions

riscv_status **riscv_mat_add_f32** (const riscv_matrix_instance_f32 * $pSrcA$, const riscv_matrix_instance_f32 * $pSrcB$, riscv_matrix_instance_f32 * $pDst$)

Floating-point matrix addition.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] $pSrcA$: points to first input matrix structure
- [in] $pSrcB$: points to second input matrix structure
- [out] $pDst$: points to output matrix structure

riscv_status **riscv_mat_add_q15** (const riscv_matrix_instance_q15 * $pSrcA$, const riscv_matrix_instance_q15 * $pSrcB$, riscv_matrix_instance_q15 * $pDst$)

Q15 matrix addition.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] $pSrcA$: points to first input matrix structure
- [in] $pSrcB$: points to second input matrix structure
- [out] $pDst$: points to output matrix structure

riscv_status **riscv_mat_add_q31** (const riscv_matrix_instance_q31 * $pSrcA$, const riscv_matrix_instance_q31 * $pSrcB$, riscv_matrix_instance_q31 * $pDst$)

Q31 matrix addition.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrcA: points to first input matrix structure
- [in] pSrcB: points to second input matrix structure
- [out] pDst: points to output matrix structure

Complex Matrix Multiplication

```
riscv_status riscv_mat_cmplx_mult_f32 (const    riscv_matrix_instance_f32    *pSrcA,
                                         const    riscv_matrix_instance_f32    *pSrcB,
                                         riscv_matrix_instance_f32 *pDst)

riscv_status riscv_mat_cmplx_mult_q15 (const    riscv_matrix_instance_q15    *pSrcA,
                                         const    riscv_matrix_instance_q15    *pSrcB,
                                         riscv_matrix_instance_q15 *pDst, q15_t *pScratch)

riscv_status riscv_mat_cmplx_mult_q31 (const    riscv_matrix_instance_q31    *pSrcA,
                                         const    riscv_matrix_instance_q31    *pSrcB,
                                         riscv_matrix_instance_q31 *pDst)
```

group CmplxMatrixMult

Complex Matrix multiplication is only defined if the number of columns of the first matrix equals the number of rows of the second matrix. Multiplying an $M \times N$ matrix with an $N \times P$ matrix results in an $M \times P$ matrix.

When matrix size checking is enabled, the functions check:

- that the inner dimensions of pSrcA and pSrcB are equal;
- that the size of the output matrix equals the outer dimensions of pSrcA and pSrcB.

Functions

```
riscv_status riscv_mat_cmplx_mult_f32 (const    riscv_matrix_instance_f32    *pSrcA,
                                         const    riscv_matrix_instance_f32    *pSrcB,
                                         riscv_matrix_instance_f32 *pDst)
```

Floating-point Complex matrix multiplication.

Floating-point, complex, matrix multiplication.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrcA: points to first input complex matrix structure
- [in] pSrcB: points to second input complex matrix structure
- [out] pDst: points to output complex matrix structure

```
riscv_status riscv_mat_cmplx_mult_q15 (const      riscv_matrix_instance_q15      *pSrcA,
                                         const      riscv_matrix_instance_q15      *pSrcB,
                                         riscv_matrix_instance_q15 *pDst, q15_t *pScratch)
```

Q15 Complex matrix multiplication.

Q15, complex, matrix multiplication.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Conditions for optimum performance Input, output and state buffers should be aligned by 32-bit

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The inputs to the multiplications are in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. This approach provides 33 guard bits and there is no risk of overflow. The 34.30 result is then truncated to 34.15 format by discarding the low 15 bits and then saturated to 1.15 format.

Parameters

- [in] pSrcA: points to first input complex matrix structure
- [in] pSrcB: points to second input complex matrix structure
- [out] pDst: points to output complex matrix structure
- [in] pScratch: points to an array for storing intermediate results

```
riscv_status riscv_mat_cmplx_mult_q31 (const      riscv_matrix_instance_q31      *pSrcA,
                                         const      riscv_matrix_instance_q31      *pSrcB,
                                         riscv_matrix_instance_q31 *pDst)
```

Q31 Complex matrix multiplication.

Q31, complex, matrix multiplication.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. The input is thus scaled down by $\log_2(\text{numColsA})$ bits to avoid overflows, as a total of numColsA additions are performed internally. The 2.62 accumulator is right shifted by 31 bits and saturated to 1.31 format to yield the final result.

Parameters

- [in] pSrcA: points to first input complex matrix structure
- [in] pSrcB: points to second input complex matrix structure
- [out] pDst: points to output complex matrix structure

Matrix Initialization

void **riscv_mat_init_f32** (riscv_matrix_instance_f32 *S, uint16_t nRows, uint16_t nColumns, float32_t *pData)

void **riscv_mat_init_f64** (riscv_matrix_instance_f64 *S, uint16_t nRows, uint16_t nColumns, float32_t *pData)

void **riscv_mat_init_q15** (riscv_matrix_instance_q15 *S, uint16_t nRows, uint16_t nColumns, q15_t *pData)

void **riscv_mat_init_q31** (riscv_matrix_instance_q31 *S, uint16_t nRows, uint16_t nColumns, q31_t *pData)

group **MatrixInit**

Initializes the underlying matrix data structure. The functions set the numRows, numCols, and pData fields of the matrix data structure.

Functions

void **riscv_mat_init_f32** (riscv_matrix_instance_f32 *S, uint16_t nRows, uint16_t nColumns, float32_t *pData)

Floating-point matrix initialization.

Return none

Parameters

- [inout] S: points to an instance of the floating-point matrix structure
- [in] nRows: number of rows in the matrix
- [in] nColumns: number of columns in the matrix
- [in] pData: points to the matrix data array

void **riscv_mat_init_f64** (riscv_matrix_instance_f64 *S, uint16_t nRows, uint16_t nColumns, float32_t *pData)

Floating-point matrix initialization.

Return none

Parameters

- [inout] S: points to an instance of the floating-point matrix structure
- [in] nRows: number of rows in the matrix
- [in] nColumns: number of columns in the matrix
- [in] pData: points to the matrix data array

void **riscv_mat_init_q15** (riscv_matrix_instance_q15 *S, uint16_t nRows, uint16_t nColumns, q15_t *pData)

Q15 matrix initialization.

Return none

Parameters

- [inout] S: points to an instance of the floating-point matrix structure
- [in] nRows: number of rows in the matrix

- [in] `nColumns`: number of columns in the matrix
- [in] `pData`: points to the matrix data array

void **riscv_mat_init_q31** (riscv_matrix_instance_q31 *S, uint16_t *nRows*, uint16_t *nColumns*, q31_t **pData*)

Q31 matrix initialization.

Return none

Parameters

- [inout] `S`: points to an instance of the Q31 matrix structure
- [in] `nRows`: number of rows in the matrix
- [in] `nColumns`: number of columns in the matrix
- [in] `pData`: points to the matrix data array

Matrix Inverse

riscv_status **riscv_mat_inverse_f32** (const riscv_matrix_instance_f32 **pSrc*, riscv_matrix_instance_f32 **pDst*)

riscv_status **riscv_mat_inverse_f64** (const riscv_matrix_instance_f64 **pSrc*, riscv_matrix_instance_f64 **pDst*)

riscv_status **riscv_mat_solve_lower_triangular_f32** (const riscv_matrix_instance_f32 **lt*, const riscv_matrix_instance_f32 **a*, riscv_matrix_instance_f32 **dst*)

riscv_status **riscv_mat_solve_lower_triangular_f64** (const riscv_matrix_instance_f64 **lt*, const riscv_matrix_instance_f64 **a*, riscv_matrix_instance_f64 **dst*)

riscv_status **riscv_mat_solve_upper_triangular_f32** (const riscv_matrix_instance_f32 **ut*, const riscv_matrix_instance_f32 **a*, riscv_matrix_instance_f32 **dst*)

riscv_status **riscv_mat_solve_upper_triangular_f64** (const riscv_matrix_instance_f64 **ut*, const riscv_matrix_instance_f64 **a*, riscv_matrix_instance_f64 **dst*)

group **MatrixInv**

Computes the inverse of a matrix.

The inverse is defined only if the input matrix is square and non-singular (the determinant is non-zero). The function checks that the input and output matrices are square and of the same size.

Matrix inversion is numerically sensitive and the NMSIS DSP library only supports matrix inversion of floating-point matrices.

Algorithm The Gauss-Jordan method is used to find the inverse. The algorithm performs a sequence of elementary row-operations until it reduces the input matrix to an identity matrix. Applying the same sequence of elementary row-operations to an identity matrix yields the inverse matrix. If the input

matrix is singular, then the algorithm terminates and returns error status RISC_V_MATH_SINGULAR.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & | & 1 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & | & 0 & 1 & 0 \\ a_{31} & a_{32} & a_{33} & | & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & | & X_{11} & X_{21} & X_{31} \\ 0 & 1 & 0 & | & X_{12} & X_{22} & X_{32} \\ 0 & 0 & 1 & | & X_{13} & X_{23} & X_{33} \end{bmatrix}$$

A is a 3 x 3 matrix and its inverse is X

Functions

riscv_status **riscv_mat_inverse_f32** (const riscv_matrix_instance_f32 *pSrc,
riscv_matrix_instance_f32 *pDst)

Floating-point matrix inverse.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed
- RISC_V_MATH_SINGULAR : Input matrix is found to be singular (non-invertible)

Parameters

- [in] pSrc: points to input matrix structure. The source matrix is modified by the function.
- [out] pDst: points to output matrix structure

riscv_status **riscv_mat_inverse_f64** (const riscv_matrix_instance_f64 *pSrc,
riscv_matrix_instance_f64 *pDst)

Floating-point (64 bit) matrix inverse.

Floating-point matrix inverse.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed
- RISC_V_MATH_SINGULAR : Input matrix is found to be singular (non-invertible)

Parameters

- [in] pSrc: points to input matrix structure. The source matrix is modified by the function.
- [out] pDst: points to output matrix structure

riscv_status **riscv_mat_solve_lower_triangular_f32** (const riscv_matrix_instance_f32
*lt, const
riscv_matrix_instance_f32 *a,
riscv_matrix_instance_f32 *dst)

Solve LT . X = A where LT is a lower triangular matrix.

Return The function returns RISC_V_MATH_SINGULAR, if the system can't be solved.

Parameters

- [in] `lt`: The lower triangular matrix
- [in] `a`: The matrix `a`
- [out] `dst`: The solution `X` of $LT \cdot X = A$

```
riscv_status riscv_mat_solve_lower_triangular_f64 (const riscv_matrix_instance_f64
                                                    *lt,                const
                                                    riscv_matrix_instance_f64 *a,
                                                    riscv_matrix_instance_f64 *dst)
```

Solve $LT \cdot X = A$ where `LT` is a lower triangular matrix.

Return The function returns `RISCV_MATH_SINGULAR`, if the system can't be solved.

Parameters

- [in] `lt`: The lower triangular matrix
- [in] `a`: The matrix `a`
- [out] `dst`: The solution `X` of $LT \cdot X = A$

```
riscv_status riscv_mat_solve_upper_triangular_f32 (const riscv_matrix_instance_f32
                                                    *ut,                const
                                                    riscv_matrix_instance_f32 *a,
                                                    riscv_matrix_instance_f32 *dst)
```

Solve $UT \cdot X = A$ where `UT` is an upper triangular matrix.

Return The function returns `RISCV_MATH_SINGULAR`, if the system can't be solved.

Parameters

- [in] `ut`: The upper triangular matrix
- [in] `a`: The matrix `a`
- [out] `dst`: The solution `X` of $UT \cdot X = A$

```
riscv_status riscv_mat_solve_upper_triangular_f64 (const riscv_matrix_instance_f64
                                                    *ut,                const
                                                    riscv_matrix_instance_f64 *a,
                                                    riscv_matrix_instance_f64 *dst)
```

Solve $UT \cdot X = A$ where `UT` is an upper triangular matrix.

Return The function returns `RISCV_MATH_SINGULAR`, if the system can't be solved.

Parameters

- [in] `ut`: The upper triangular matrix
- [in] `a`: The matrix `a`
- [out] `dst`: The solution `X` of $UT \cdot X = A$

Matrix Multiplication

```
riscv_status riscv_mat_mult_f32 (const riscv_matrix_instance_f32 *pSrcA, const
                                riscv_matrix_instance_f32 *pSrcB, riscv_matrix_instance_f32

                                *pDst, q7_t *pState)

```

group **MatrixMult**

Multiplies two matrices.

Matrix multiplication is only defined if the number of columns of the first matrix equals the number of rows of the second matrix. Multiplying an $M \times N$ matrix with an $N \times P$ matrix results in an $M \times P$ matrix. When matrix size checking is enabled, the functions check: (1) that the inner dimensions of `pSrcA` and `pSrcB` are equal; and (2) that the size of the output matrix equals the outer dimensions of `pSrcA` and `pSrcB`.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \times \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix} = \begin{bmatrix} a_{11} \times b_{11} + a_{12} \times b_{21} + a_{13} \times b_{31} & a_{11} \times b_{12} + a_{12} \times b_{22} + a_{13} \times b_{32} & a_{11} \times b_{13} + a_{12} \times b_{23} + a_{13} \times b_{33} \\ a_{21} \times b_{11} + a_{22} \times b_{21} + a_{23} \times b_{31} & a_{21} \times b_{12} + a_{22} \times b_{22} + a_{23} \times b_{32} & a_{21} \times b_{13} + a_{22} \times b_{23} + a_{23} \times b_{33} \\ a_{31} \times b_{11} + a_{32} \times b_{21} + a_{33} \times b_{31} & a_{31} \times b_{12} + a_{32} \times b_{22} + a_{33} \times b_{32} & a_{31} \times b_{13} + a_{32} \times b_{23} + a_{33} \times b_{33} \end{bmatrix}$$

Functions

```

riscv_status riscv_mat_mult_f32 (const      riscv_matrix_instance_f32      *pSrcA,      const
                                riscv_matrix_instance_f32      *pSrcB,      riscv_matrix_instance_f32
                                *pDst)

```

Floating-point matrix multiplication.

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `*pSrcA`: points to the first input matrix structure
- [in] `*pSrcB`: points to the second input matrix structure
- [out] `*pDst`: points to output matrix structure

```

riscv_status riscv_mat_mult_f64 (const      riscv_matrix_instance_f64      *pSrcA,      const
                                riscv_matrix_instance_f64      *pSrcB,      riscv_matrix_instance_f64
                                *pDst)

```

Floating-point matrix multiplication.

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `*pSrcA`: points to the first input matrix structure
- [in] `*pSrcB`: points to the second input matrix structure
- [out] `*pDst`: points to output matrix structure

```
riscv_status riscv_mat_mult_fast_q15 (const    riscv_matrix_instance_q15    *pSrcA,
                                       const    riscv_matrix_instance_q15    *pSrcB,
                                       riscv_matrix_instance_q15 *pDst, q15_t *pState)
```

Q15 matrix multiplication (fast variant).

Q15 matrix multiplication (fast variant) for RISC-V Core with DSP enabled.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_SIZE_MISMATCH` : Matrix size check failed

Scaling and Overflow Behavior The difference between the function `riscv_mat_mult_q15()` and this fast variant is that the fast variant use a 32-bit rather than a 64-bit accumulator. The result of each 1.15 x 1.15 multiplication is truncated to 2.30 format. These intermediate results are accumulated in a 32-bit register in 2.30 format. Finally, the accumulator is saturated and converted to a 1.15 result.

The fast version has the same overflow behavior as the standard version but provides less precision since it discards the low 16 bits of each multiplication result. In order to avoid overflows completely the input signals must be scaled down. Scale down one of the input matrices by $\log_2(\text{numColsA})$ bits to avoid overflows, as a total of `numColsA` additions are computed internally for each output element.

Remark Refer to `riscv_mat_mult_q15()` for a slower implementation of this function which uses 64-bit accumulation to provide higher precision.

Parameters

- [in] `pSrcA`: points to the first input matrix structure
- [in] `pSrcB`: points to the second input matrix structure
- [out] `pDst`: points to output matrix structure
- [in] `pState`: points to the array for storing intermediate results

```
riscv_status riscv_mat_mult_fast_q31 (const    riscv_matrix_instance_q31    *pSrcA,
                                       const    riscv_matrix_instance_q31    *pSrcB,
                                       riscv_matrix_instance_q31 *pDst)
```

Q31 matrix multiplication (fast variant).

Q31 matrix multiplication (fast variant) for RISC-V Core with DSP enabled.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_SIZE_MISMATCH` : Matrix size check failed

Scaling and Overflow Behavior The difference between the function `riscv_mat_mult_q31()` and this fast variant is that the fast variant use a 32-bit rather than a 64-bit accumulator. The result of each 1.31 x 1.31 multiplication is truncated to 2.30 format. These intermediate results are accumulated in a 32-bit register in 2.30 format. Finally, the accumulator is saturated and converted to a 1.31 result.

The fast version has the same overflow behavior as the standard version but provides less precision since it discards the low 32 bits of each multiplication result. In order to avoid overflows completely the input signals must be scaled down. Scale down one of the input matrices by $\log_2(\text{numColsA})$ bits to avoid overflows, as a total of numColsA additions are computed internally for each output element.

Remark Refer to `riscv_mat_mult_q31()` for a slower implementation of this function which uses 64-bit accumulation to provide higher precision.

Parameters

- [in] `pSrcA`: points to the first input matrix structure
- [in] `pSrcB`: points to the second input matrix structure
- [out] `pDst`: points to output matrix structure

```
riscv_status riscv_mat_mult_q15(const   riscv_matrix_instance_q15   *pSrcA,   const
                                riscv_matrix_instance_q15   *pSrcB, riscv_matrix_instance_q15
                                *pDst, q15_t *pState)
```

Q15 matrix multiplication.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_SIZE_MISMATCH` : Matrix size check failed

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The inputs to the multiplications are in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. This approach provides 33 guard bits and there is no risk of overflow. The 34.30 result is then truncated to 34.15 format by discarding the low 15 bits and then saturated to 1.15 format.

Refer to `riscv_mat_mult_fast_q15()` for a faster but less precise version of this function.

Parameters

- [in] `pSrcA`: points to the first input matrix structure
- [in] `pSrcB`: points to the second input matrix structure
- [out] `pDst`: points to output matrix structure
- [in] `pState`: points to the array for storing intermediate results (Unused)

```
riscv_status riscv_mat_mult_q31(const   riscv_matrix_instance_q31   *pSrcA,   const
                                riscv_matrix_instance_q31   *pSrcB, riscv_matrix_instance_q31
                                *pDst)
```

Q31 matrix multiplication.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_SIZE_MISMATCH` : Matrix size check failed

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. There is no saturation on intermediate additions. Thus, if the accumulator overflows it wraps around and distorts the result. The input signals should be scaled down to avoid intermediate overflows. The input is thus scaled down by $\log_2(\text{numColsA})$ bits to avoid overflows, as a total of numColsA additions are performed internally. The 2.62 accumulator is right shifted by 31 bits and saturated to 1.31 format to yield the final result.

Remark Refer to `riscv_mat_mult_fast_q31()` for a faster but less precise implementation of this function.

Parameters

- [in] `pSrcA`: points to the first input matrix structure
- [in] `pSrcB`: points to the second input matrix structure
- [out] `pDst`: points to output matrix structure

```
riscv_status riscv_mat_mult_q7 (const    riscv_matrix_instance_q7    *pSrcA,    const
                                riscv_matrix_instance_q7    *pSrcB,    riscv_matrix_instance_q7
                                *pDst, q7_t *pState)
```

Q7 matrix multiplication.

Scaling and Overflow Behavior:

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `*pSrcA`: points to the first input matrix structure
- [in] `*pSrcB`: points to the second input matrix structure
- [out] `*pDst`: points to output matrix structure
- [in] `*pState`: points to the array for storing intermediate results (Unused in some versions)

The function is implemented using a 32-bit internal accumulator saturated to 1.7 format.

Matrix Scale

```
riscv_status riscv_mat_scale_f32 (const    riscv_matrix_instance_f32    *pSrc,    float32_t    scale,
                                riscv_matrix_instance_f32    *pDst)
```

```
riscv_status riscv_mat_scale_q15 (const    riscv_matrix_instance_q15    *pSrc,    q15_t    scaleFract,    int32_t
                                shift,    riscv_matrix_instance_q15    *pDst)
```

```
riscv_status riscv_mat_scale_q31 (const    riscv_matrix_instance_q31    *pSrc,    q31_t    scaleFract,    int32_t
                                shift,    riscv_matrix_instance_q31    *pDst)
```

group **MatrixScale**

Multiplies a matrix by a scalar. This is accomplished by multiplying each element in the matrix by the scalar. For example: The function checks to make sure that the input and output matrices are of the same size.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \times K = \begin{bmatrix} a_{11} \times K & a_{12} \times K & a_{13} \times K \\ a_{21} \times K & a_{22} \times K & a_{23} \times K \\ a_{31} \times K & a_{32} \times K & a_{33} \times K \end{bmatrix}$$

In the fixed-point Q15 and Q31 functions, `scale` is represented by a fractional multiplication `scaleFract` and an arithmetic shift `shift`. The shift allows the gain of the scaling operation to exceed 1.0. The overall scale factor applied to the fixed-point data is

Functions

riscv_status **riscv_mat_scale_f32** (**const** riscv_matrix_instance_f32 *pSrc, float32_t scale, riscv_matrix_instance_f32 *pDst)

Floating-point matrix scaling.

Return execution status

- RISCVMATH_SUCCESS : Operation successful
- RISCVMATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrc: points to input matrix
- [in] scale: scale factor to be applied
- [out] pDst: points to output matrix structure

riscv_status **riscv_mat_scale_q15** (**const** riscv_matrix_instance_q15 *pSrc, q15_t scaleFract, int32_t shift, riscv_matrix_instance_q15 *pDst)

Q15 matrix scaling.

Return execution status

- RISCVMATH_SUCCESS : Operation successful
- RISCVMATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The input data *pSrc and scaleFract are in 1.15 format. These are multiplied to yield a 2.30 intermediate result and this is shifted with saturation to 1.15 format.

Parameters

- [in] pSrc: points to input matrix
- [in] scaleFract: fractional portion of the scale factor
- [in] shift: number of bits to shift the result by
- [out] pDst: points to output matrix structure

riscv_status **riscv_mat_scale_q31** (**const** riscv_matrix_instance_q31 *pSrc, q31_t scaleFract, int32_t shift, riscv_matrix_instance_q31 *pDst)

Q31 matrix scaling.

Return execution status

- RISCVMATH_SUCCESS : Operation successful
- RISCVMATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The input data *pSrc and scaleFract are in 1.31 format. These are multiplied to yield a 2.62 intermediate result which is shifted with saturation to 1.31 format.

Parameters

- [in] pSrc: points to input matrix
- [in] scaleFract: fractional portion of the scale factor
- [in] shift: number of bits to shift the result by
- [out] pDst: points to output matrix structure

Matrix Subtraction

```
riscv_status riscv_mat_sub_f32 (const    riscv_matrix_instance_f32    *pSrcA,    const
                                riscv_matrix_instance_f32 *pSrcB, riscv_matrix_instance_f32 *pDst)
riscv_status riscv_mat_sub_f64 (const    riscv_matrix_instance_f64    *pSrcA,    const
                                riscv_matrix_instance_f64 *pSrcB, riscv_matrix_instance_f64 *pDst)
riscv_status riscv_mat_sub_q15 (const    riscv_matrix_instance_q15    *pSrcA,    const
                                riscv_matrix_instance_q15 *pSrcB, riscv_matrix_instance_q15 *pDst)
riscv_status riscv_mat_sub_q31 (const    riscv_matrix_instance_q31    *pSrcA,    const
                                riscv_matrix_instance_q31 *pSrcB, riscv_matrix_instance_q31 *pDst)
```

group **MatrixSub**

Subtract two matrices. The functions check to make sure that pSrcA, pSrcB, and pDst have the same number of rows and columns.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} - \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix} = \begin{bmatrix} a_{11}-b_{11} & a_{12}-b_{12} & a_{13}-b_{13} \\ a_{21}-b_{21} & a_{22}-b_{22} & a_{23}-b_{23} \\ a_{31}-b_{31} & a_{32}-b_{32} & a_{33}-b_{33} \end{bmatrix}$$

Functions

```
riscv_status riscv_mat_sub_f32 (const    riscv_matrix_instance_f32    *pSrcA,    const
                                riscv_matrix_instance_f32 *pSrcB, riscv_matrix_instance_f32
                                *pDst)
```

Floating-point matrix subtraction.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrcA: points to the first input matrix structure
- [in] pSrcB: points to the second input matrix structure
- [out] pDst: points to output matrix structure

```
riscv_status riscv_mat_sub_f64 (const    riscv_matrix_instance_f64    *pSrcA,    const
                                riscv_matrix_instance_f64 *pSrcB, riscv_matrix_instance_f64
                                *pDst)
```

Floating-point matrix subtraction.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrcA: points to the first input matrix structure

- [in] pSrcB: points to the second input matrix structure
- [out] pDst: points to output matrix structure

```
riscv_status riscv_mat_sub_q15 (const riscv_matrix_instance_q15 *pSrcA, const  
                                riscv_matrix_instance_q15 *pSrcB, riscv_matrix_instance_q15  
                                *pDst)
```

Q15 matrix subtraction.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Parameters

- [in] pSrcA: points to the first input matrix structure
- [in] pSrcB: points to the second input matrix structure
- [out] pDst: points to output matrix structure

```
riscv_status riscv_mat_sub_q31 (const riscv_matrix_instance_q31 *pSrcA, const  
                                riscv_matrix_instance_q31 *pSrcB, riscv_matrix_instance_q31  
                                *pDst)
```

Q31 matrix subtraction.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Parameters

- [in] pSrcA: points to the first input matrix structure
- [in] pSrcB: points to the second input matrix structure
- [out] pDst: points to output matrix structure

Matrix Transpose

```
riscv_status riscv_mat_trans_f32 (const riscv_matrix_instance_f32 *pSrc, riscv_matrix_instance_f32  
                                *pDst)
```

```
riscv_status riscv_mat_trans_f64 (const riscv_matrix_instance_f64 *pSrc, riscv_matrix_instance_f64  
                                *pDst)
```

```
riscv_status riscv_mat_trans_q15 (const riscv_matrix_instance_q15 *pSrc, riscv_matrix_instance_q15  
                                *pDst)
```

```
riscv_status riscv_mat_trans_q31 (const riscv_matrix_instance_q31 *pSrc, riscv_matrix_instance_q31  
                                *pDst)
```

```
riscv_status riscv_mat_trans_q7 (const riscv_matrix_instance_q7 *pSrc, riscv_matrix_instance_q7  
                                *pDst)
```

group MatrixTrans

Tranposes a matrix.

Transposing an $M \times N$ matrix flips it around the center diagonal and results in an $N \times M$ matrix.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}^T = \begin{bmatrix} a_{11} & a_{21} & a_{31} \\ a_{12} & a_{22} & a_{32} \\ a_{13} & a_{23} & a_{33} \end{bmatrix}$$

Functions

riscv_status **riscv_mat_trans_f32** (const riscv_matrix_instance_f32 *pSrc,
riscv_matrix_instance_f32 *pDst)

Floating-point matrix transpose.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrc: points to input matrix
- [out] pDst: points to output matrix

riscv_status **riscv_mat_trans_f64** (const riscv_matrix_instance_f64 *pSrc,
riscv_matrix_instance_f64 *pDst)

Floating-point matrix transpose.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrc: points to input matrix
- [out] pDst: points to output matrix

riscv_status **riscv_mat_trans_q15** (const riscv_matrix_instance_q15 *pSrc,
riscv_matrix_instance_q15 *pDst)

Q15 matrix transpose.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful

- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrc: points to input matrix
- [out] pDst: points to output matrix

riscv_status **riscv_mat_trans_q31** (const riscv_matrix_instance_q31 *pSrc,
riscv_matrix_instance_q31 *pDst)
Q31 matrix transpose.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrc: points to input matrix
- [out] pDst: points to output matrix

riscv_status **riscv_mat_trans_q7** (const riscv_matrix_instance_q7 *pSrc,
riscv_matrix_instance_q7 *pDst)
Q7 matrix transpose.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_SIZE_MISMATCH : Matrix size check failed

Parameters

- [in] pSrc: points to input matrix
- [out] pDst: points to output matrix

group groupMatrix

This set of functions provides basic matrix math operations. The functions operate on matrix data structures. For example, the type definition for the floating-point matrix structure is shown below: There are similar definitions for Q15 and Q31 data types.

The structure specifies the size of the matrix and then points to an array of data. The array is of size numRows X numCols and the values are arranged in row order. That is, the matrix element (i, j) is stored at:

Init Functions There is an associated initialization function for each type of matrix data structure. The initialization function sets the values of the internal structure fields. Refer to riscv_mat_init_f32(), riscv_mat_init_q31() and riscv_mat_init_q15() for floating-point, Q31 and Q15 types, respectively.

Use of the initialization function is optional. However, if initialization function is used then the instance structure cannot be placed into a const data section. To place the instance structure in a const data section, manually initialize the data structure. For example: where numRows specifies the number of rows, numColumns specifies the number of columns, and pData points to the data array.

Size Checking By default all of the matrix functions perform size checking on the input and output matrices. For example, the matrix addition function verifies that the two input matrices and the output matrix all have the same number of rows and columns. If the size check fails the functions return: Otherwise the functions return There is some overhead associated with this matrix size checking. The matrix size checking is enabled via the #define within the library project settings. By default this macro is defined and size checking is enabled. By changing the project settings and undefining this macro size checking

is eliminated and the functions run a bit faster. With size checking disabled the functions always return `RISCV_MATH_SUCCESS`.

group **ComplexFFT**

The Fast Fourier Transform (FFT) is an efficient algorithm for computing the Discrete Fourier Transform (DFT). The FFT can be orders of magnitude faster than the DFT, especially for long lengths. The algorithms described in this section operate on complex data. A separate set of functions is devoted to handling of real sequences.

There are separate algorithms for handling floating-point, Q15, and Q31 data types. The algorithms available for each data type are described next.

The FFT functions operate in-place. That is, the array holding the input data will also be used to hold the corresponding result. The input data is complex and contains $2 * \text{fftLen}$ interleaved values as shown

below. The FFT result will be contained in the same array and the frequency domain values will have the same interleaving.

Floating-point The floating-point complex FFT uses a mixed-radix algorithm. Multiple radix-8 stages are performed along with a single radix-2 or radix-4 stage, as needed. The algorithm supports lengths of [16, 32, 64, ..., 4096] and each length uses a different twiddle factor table.

The function uses the standard FFT definition and output values may grow by a factor of `fftLen` when computing the forward transform. The inverse transform includes a scale of $1/\text{fftLen}$ as part of the calculation and this matches the textbook definition of the inverse FFT.

For the MVE version, the new `riscv_cfft_init_f32` initialization function is **mandatory**. **Compilation flags are available to include only the required tables for the needed FFTs**. Other FFT versions can continue to be initialized as explained below.

For not MVE versions, pre-initialized data structures containing twiddle factors and bit reversal tables are provided and defined in `riscv_const_structs.h`. Include this header in your function and then pass one of the constant structures as an argument to `riscv_cfft_f32`. For example:

```
riscv_cfft_f32(riscv_cfft_sR_f32_len64, pSrc, 1, 1)
```

computes a 64-point inverse complex FFT including bit reversal. The data structures are treated as constant data and not modified during the calculation. The same data structure can be reused for multiple transforms including mixing forward and inverse transforms.

Earlier releases of the library provided separate radix-2 and radix-4 algorithms that operated on floating-point data. These functions are still provided but are deprecated. The older functions are slower and less general than the new functions.

An example of initialization of the constants for the `riscv_cfft_f32` function follows:

```
const static riscv_cfft_instance_f32 *S;
...
switch (length) {
    case 16:
        S = &riscv_cfft_sR_f32_len16;
        break;
    case 32:
        S = &riscv_cfft_sR_f32_len32;
        break;
    case 64:
        S = &riscv_cfft_sR_f32_len64;
        break;
    case 128:
        S = &riscv_cfft_sR_f32_len128;
        break;
    case 256:
        S = &riscv_cfft_sR_f32_len256;
        break;
    case 512:
        S = &riscv_cfft_sR_f32_len512;
        break;
    case 1024:
        S = &riscv_cfft_sR_f32_len1024;
        break;
    case 2048:
        S = &riscv_cfft_sR_f32_len2048;
        break;
    case 4096:
        S = &riscv_cfft_sR_f32_len4096;
```

(continues on next page)

(continued from previous page)

```

    break;
}

```

The new `riscv_cfft_init_f32` can also be used.

Q15 and Q31 The floating-point complex FFT uses a mixed-radix algorithm. Multiple radix-4 stages are performed along with a single radix-2 stage, as needed. The algorithm supports lengths of [16, 32, 64, ..., 4096] and each length uses a different twiddle factor table.

The function uses the standard FFT definition and output values may grow by a factor of `fftLen` when computing the forward transform. The inverse transform includes a scale of $1/\text{fftLen}$ as part of the calculation and this matches the textbook definition of the inverse FFT.

Pre-initialized data structures containing twiddle factors and bit reversal tables are provided and defined in `riscv_const_structs.h`. Include this header in your function and then pass one of the constant structures as an argument to `riscv_cfft_q31`. For example:

```
riscv_cfft_q31(riscv_cfft_sR_q31_len64, pSrc, 1, 1)
```

computes a 64-point inverse complex FFT including bit reversal. The data structures are treated as constant data and not modified during the calculation. The same data structure can be reused for multiple transforms including mixing forward and inverse transforms.

Earlier releases of the library provided separate radix-2 and radix-4 algorithms that operated on floating-point data. These functions are still provided but are deprecated. The older functions are slower and less general than the new functions.

An example of initialization of the constants for the `riscv_cfft_q31` function follows:

```

const static riscv_cfft_instance_q31 *S;
...
switch (length) {
    case 16:
        S = &riscv_cfft_sR_q31_len16;
        break;
    case 32:
        S = &riscv_cfft_sR_q31_len32;
        break;
    case 64:
        S = &riscv_cfft_sR_q31_len64;
        break;
    case 128:
        S = &riscv_cfft_sR_q31_len128;
        break;
    case 256:
        S = &riscv_cfft_sR_q31_len256;
        break;
    case 512:
        S = &riscv_cfft_sR_q31_len512;
        break;
    case 1024:
        S = &riscv_cfft_sR_q31_len1024;
        break;
    case 2048:
        S = &riscv_cfft_sR_q31_len2048;
        break;
    case 4096:
        S = &riscv_cfft_sR_q31_len4096;

```

(continues on next page)

(continued from previous page)

```

    break;
}

```

Functions

void **riscv_cfft_f32** (**const** riscv_cfft_instance_f32 *S, float32_t *p1, uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Processing function for the floating-point complex FFT.

Return none

Parameters

- [in] S: points to an instance of the floating-point CFFT structure
- [inout] p1: points to the complex data buffer of size 2*fftLen. Processing occurs in-place
- [in] ifftFlag: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] bitReverseFlag: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

void **riscv_cfft_f64** (**const** riscv_cfft_instance_f64 *S, float64_t *p1, uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Processing function for the Double Precision floating-point complex FFT.

Return none

Parameters

- [in] S: points to an instance of the Double Precision floating-point CFFT structure
- [inout] p1: points to the complex data buffer of size 2*fftLen. Processing occurs in-place
- [in] ifftFlag: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] bitReverseFlag: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

riscv_status **riscv_cfft_init_f32** (riscv_cfft_instance_f32 *S, uint16_t *fftLen*)

Initialization function for the cfft f32 function.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Use of this function is mandatory only for the MVE version of the FFT. Other versions can still initialize directly the data structure using variables declared in `riscv_const_structs.h`

Parameters

- [inout] `S`: points to an instance of the floating-point CFFT structure
- [in] `fftLen`: fft length (number of complex samples)

riscv_status **riscv_cfft_init_f64** (riscv_cfft_instance_f64 *`S`, uint16_t `fftLen`)
Initialization function for the cfft f64 function.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Use of this function is mandatory only for the MVE version of the FFT. Other versions can still initialize directly the data structure using variables declared in `riscv_const_structs.h`

Parameters

- [inout] `S`: points to an instance of the floating-point CFFT structure
- [in] `fftLen`: fft length (number of complex samples)

riscv_status **riscv_cfft_init_q15** (riscv_cfft_instance_q15 *`S`, uint16_t `fftLen`)
Initialization function for the cfft q15 function.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Use of this function is mandatory only for the MVE version of the FFT. Other versions can still initialize directly the data structure using variables declared in `riscv_const_structs.h`

Parameters

- [inout] `S`: points to an instance of the floating-point CFFT structure
- [in] `fftLen`: fft length (number of complex samples)

riscv_status **riscv_cfft_init_q31** (riscv_cfft_instance_q31 *`S`, uint16_t `fftLen`)
Initialization function for the cfft q31 function.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Use of this function is mandatory only for the MVE version of the FFT. Other versions can still initialize directly the data structure using variables declared in `riscv_const_structs.h`

Parameters

- [inout] `S`: points to an instance of the floating-point CFFT structure
- [in] `fftLen`: fft length (number of complex samples)

void **riscv_cfft_q15** (**const** riscv_cfft_instance_q15 *S, q15_t *p1, uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Processing function for Q15 complex FFT.

Return none

Parameters

- [in] S: points to an instance of Q15 CFFT structure
- [inout] p1: points to the complex data buffer of size 2*fftLen. Processing occurs in-place
- [in] ifftFlag: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] bitReverseFlag: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

void **riscv_cfft_q31** (**const** riscv_cfft_instance_q31 *S, q31_t *p1, uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Processing function for the Q31 complex FFT.

Return none

Parameters

- [in] S: points to an instance of the fixed-point CFFT structure
- [inout] p1: points to the complex data buffer of size 2*fftLen. Processing occurs in-place
- [in] ifftFlag: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] bitReverseFlag: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

void **riscv_cfft_radix2_f32** (**const** riscv_cfft_radix2_instance_f32 *S, float32_t *pSrc)

Radix-2 CFFT/CIFFT.

Return none

Parameters

- [in] S: points to an instance of the floating-point Radix-2 CFFT/CIFFT structure
- [inout] pSrc: points to the complex data buffer of size 2*fftLen. Processing occurs in-place

riscv_status **riscv_cfft_radix2_init_f32** (riscv_cfft_radix2_instance_f32 *S, uint16_t *fftLen*,
uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Initialization function for the floating-point CFFT/CIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : `fftLen` is not a supported length

Details The parameter `ifftFlag` controls whether a forward or inverse transform is computed. Set(=1) `ifftFlag` for calculation of CIFFT otherwise CFFT is calculated

The parameter `bitReverseFlag` controls whether output is in normal order or bit reversed order. Set(=1) `bitReverseFlag` for output to be in normal order otherwise output is in bit reversed order.

The parameter `fftLen` Specifies length of CFFT/CIFFT process. Supported FFT Lengths are 16, 64, 256, 1024.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] `S`: points to an instance of the floating-point CFFT/CIFFT structure
- [in] `fftLen`: length of the FFT
- [in] `ifftFlag`: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] `bitReverseFlag`: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

riscv_status **riscv_cfft_radix2_init_q15** (riscv_cfft_radix2_instance_q15 **S*, uint16_t *fftLen*,
uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Initialization function for the Q15 CFFT/CIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : `fftLen` is not a supported length

Details The parameter `ifftFlag` controls whether a forward or inverse transform is computed. Set(=1) `ifftFlag` for calculation of CIFFT otherwise CFFT is calculated

The parameter `bitReverseFlag` controls whether output is in normal order or bit reversed order. Set(=1) `bitReverseFlag` for output to be in normal order otherwise output is in bit reversed order.

The parameter `fftLen` Specifies length of CFFT/CIFFT process. Supported FFT Lengths are 16, 64, 256, 1024.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] `S`: points to an instance of the Q15 CFFT/CIFFT structure.
- [in] `fftLen`: length of the FFT.
- [in] `ifftFlag`: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] `bitReverseFlag`: flag that enables / disables bit reversal of output

- value = 0: disables bit reversal of output
- value = 1: enables bit reversal of output

riscv_status **riscv_cfft_radix2_init_q31** (riscv_cfft_radix2_instance_q31 *S, uint16_t fftLen, uint8_t ifftFlag, uint8_t bitReverseFlag)

Initialization function for the Q31 CFFT/CIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : fftLen is not a supported length

Details The parameter ifftFlag controls whether a forward or inverse transform is computed. Set(=1) ifftFlag for calculation of CIFFT otherwise CFFT is calculated

The parameter bitReverseFlag controls whether output is in normal order or bit reversed order. Set(=1) bitReverseFlag for output to be in normal order otherwise output is in bit reversed order.

The parameter fftLen Specifies length of CFFT/CIFFT process. Supported FFT Lengths are 16, 64, 256, 1024.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] S: points to an instance of the Q31 CFFT/CIFFT structure
- [in] fftLen: length of the FFT
- [in] ifftFlag: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] bitReverseFlag: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

void **riscv_cfft_radix2_q15** (const riscv_cfft_radix2_instance_q15 *S, q15_t *pSrc)
Processing function for the fixed-point CFFT/CIFFT.

Return none

Parameters

- [in] S: points to an instance of the fixed-point CFFT/CIFFT structure
- [inout] pSrc: points to the complex data buffer of size 2*fftLen. Processing occurs in-place

void **riscv_cfft_radix2_q31** (const riscv_cfft_radix2_instance_q31 *S, q31_t *pSrc)
Processing function for the fixed-point CFFT/CIFFT.

Return none

Parameters

- [in] S: points to an instance of the fixed-point CFFT/CIFFT structure

- [inout] pSrc: points to the complex data buffer of size 2*fftLen. Processing occurs in-place

void **riscv_cfft_radix4_f32** (const riscv_cfft_radix4_instance_f32 *S, float32_t *pSrc)

Processing function for the floating-point Radix-4 CFFT/CIFFT.

Return none

Parameters

- [in] S: points to an instance of the floating-point Radix-4 CFFT/CIFFT structure
- [inout] pSrc: points to the complex data buffer of size 2*fftLen. Processing occurs in-place

riscv_status **riscv_cfft_radix4_init_f32** (riscv_cfft_radix4_instance_f32 *S, uint16_t fftLen, uint8_t ifftFlag, uint8_t bitReverseFlag)

Initialization function for the floating-point CFFT/CIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : fftLen is not a supported length

Details The parameter ifftFlag controls whether a forward or inverse transform is computed. Set(=1) ifftFlag for calculation of CIFFT otherwise CFFT is calculated

The parameter bitReverseFlag controls whether output is in normal order or bit reversed order. Set(=1) bitReverseFlag for output to be in normal order otherwise output is in bit reversed order.

The parameter fftLen Specifies length of CFFT/CIFFT process. Supported FFT Lengths are 16, 64, 256, 1024.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] S: points to an instance of the floating-point CFFT/CIFFT structure
- [in] fftLen: length of the FFT
- [in] ifftFlag: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] bitReverseFlag: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

riscv_status **riscv_cfft_radix4_init_q15** (riscv_cfft_radix4_instance_q15 *S, uint16_t fftLen, uint8_t ifftFlag, uint8_t bitReverseFlag)

Initialization function for the Q15 CFFT/CIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : fftLen is not a supported length

Details The parameter `ifftFlag` controls whether a forward or inverse transform is computed. Set(=1) `ifftFlag` for calculation of CFFT otherwise CFFT is calculated

The parameter `bitReverseFlag` controls whether output is in normal order or bit reversed order. Set(=1) `bitReverseFlag` for output to be in normal order otherwise output is in bit reversed order.

The parameter `fftLen` Specifies length of CFFT/CFFT process. Supported FFT Lengths are 16, 64, 256, 1024.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] `S`: points to an instance of the Q15 CFFT/CFFT structure
- [in] `fftLen`: length of the FFT
- [in] `ifftFlag`: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] `bitReverseFlag`: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

riscv_status **riscv_cfft_radix4_init_q31** (riscv_cfft_radix4_instance_q31 **S*, uint16_t *fftLen*,
uint8_t *ifftFlag*, uint8_t *bitReverseFlag*)

Initialization function for the Q31 CFFT/CFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : `fftLen` is not a supported length

Details The parameter `ifftFlag` controls whether a forward or inverse transform is computed. Set(=1) `ifftFlag` for calculation of CFFT otherwise CFFT is calculated

The parameter `bitReverseFlag` controls whether output is in normal order or bit reversed order. Set(=1) `bitReverseFlag` for output to be in normal order otherwise output is in bit reversed order.

The parameter `fftLen` Specifies length of CFFT/CFFT process. Supported FFT Lengths are 16, 64, 256, 1024.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] `S`: points to an instance of the Q31 CFFT/CFFT structure.
- [in] `fftLen`: length of the FFT.
- [in] `ifftFlag`: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] `bitReverseFlag`: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

void **riscv_cfft_radix4_q15** (const riscv_cfft_radix4_instance_q15 *S, q15_t *pSrc)

Processing function for the Q15 CFFT/CIFFT.

Return none

Input and output formats: Internally input is downscaled by 2 for every stage to avoid saturations inside CFFT/CIFFT process. Hence the output format is different for different FFT sizes. The input and output formats for different FFT sizes and number of bits to upscale are mentioned in the tables below for CFFT and CIFFT:

CFFT Size	Input format	Output Format	Number of bits to upscale
16	1.15	5.11	4
64	1.15	7.9	6
256	1.15	9.7	8
1024	1.15	11.5	10

CIFFT Size
16
64
256
1024

Parameters

- [in] S: points to an instance of the Q15 CFFT/CIFFT structure.
- [inout] pSrc: points to the complex data buffer. Processing occurs in-place.

void **riscv_cfft_radix4_q31** (const riscv_cfft_radix4_instance_q31 *S, q31_t *pSrc)

Processing function for the Q31 CFFT/CIFFT.

Return none

Input and output formats: Internally input is downscaled by 2 for every stage to avoid saturations inside CFFT/CIFFT process. Hence the output format is different for different FFT sizes. The input and output formats for different FFT sizes and number of bits to upscale are mentioned in the tables below for CFFT and CIFFT:

CFFT Size	Input format	Output Format	Number of bits to upscale
16	1.31	5.27	4
64	1.31	7.25	6
256	1.31	9.23	8
1024	1.31	11.21	10

CIFFT Size
16
64
256
1024

Parameters

- [in] S: points to an instance of the Q31 CFFT/CIFFT structure
- [inout] pSrc: points to the complex data buffer of size 2*fftLen. Processing occurs in-place

group DCT4_IDCT4

Representation of signals by minimum number of values is important for storage and transmission. The possibility of large discontinuity between the beginning and end of a period of a signal in DFT can be avoided by extending the signal so that it is even-symmetric. Discrete Cosine Transform (DCT) is constructed such that its energy is heavily concentrated in the lower part of the spectrum and is very widely used in signal and image coding applications. The family of DCTs (DCT type- 1,2,3,4) is the outcome of different combinations of homogeneous boundary conditions. DCT has an excellent energy-packing capability, hence has many applications and in data compression in particular.

DCT is essentially the Discrete Fourier Transform(DFT) of an even-extended real signal. Reordering of the input data makes the computation of DCT just a problem of computing the DFT of a real signal with a few additional operations. This approach provides regular, simple, and very efficient DCT algorithms for practical hardware and software implementations.

DCT type-II can be implemented using Fast fourier transform (FFT) internally, as the transform is applied on real values, Real FFT can be used. DCT4 is implemented using DCT2 as their implementations are similar except with some added pre-processing and post-processing. DCT2 implementation can be described in the following steps:

- Re-ordering input
- Calculating Real FFT
- Multiplication of weights and Real FFT output and getting real part from the product.

This process is explained by the block diagram below:

Algorithm The N-point type-IV DCT is defined as a real, linear transformation by the formula: where $k = 0, 1, 2, \dots, N-1$

$$X_c(k) = \sqrt{\frac{2}{N}} \sum_{n=0}^{N-1} x(n) \cos \left[\left(n + \frac{1}{2} \right) \left(k + \frac{1}{2} \right) \frac{\pi}{N} \right]$$

Its inverse is defined as follows: where $n = 0, 1, 2, \dots, N-1$

$$x(n) = \sqrt{\frac{2}{N}} \sum_{k=0}^{N-1} X_c(k) \cos \left[\left(n + \frac{1}{2} \right) \left(k + \frac{1}{2} \right) \frac{\pi}{N} \right]$$

The DCT4 matrices become involutory (i.e. they are self-inverse) by multiplying with an overall scale factor of $\sqrt{2/N}$. The symmetry of the transform matrix indicates that the fast algorithms for the forward and inverse transform computation are identical. Note that the implementation of Inverse DCT4 and DCT4 is same, hence same process function can be used for both.

Lengths supported by the transform: As DCT4 internally uses Real FFT, it supports all the lengths 128, 512, 2048 and 8192. The library provides separate functions for Q15, Q31, and floating-point data types.

Instance Structure The instances for Real FFT and FFT, cosine values table and twiddle factor table are stored in an instance data structure. A separate instance structure must be defined for each transform. There are separate instance structure declarations for each of the 3 supported data types.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Initializes Real FFT as its process function is used internally in DCT4, by calling `riscv_rfft_init_f32()`.

Use of the initialization function is optional. However, if the initialization function is used, then the instance structure cannot be placed into a const data section. To place an instance structure into a const data section, the instance structure must be manually initialized. Manually initialize the instance structure as follows: where `N` is the length of the DCT4; `Nby2` is half of the length of the DCT4; `normalize` is normalizing factor used and is equal to $\sqrt{2/N}$; `pTwiddle` points to the twiddle factor table; `pCosFactor` points to the cosFactor table; `pRfft` points to the real FFT instance; `pCfft` points to the complex FFT instance; The CFFT and RFFT structures also needs to be initialized, refer to `riscv_cfft_radix4_f32()` and `riscv_rfft_f32()` respectively for details regarding static initialization.

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the DCT4 transform functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

void **riscv_dct4_f32** (**const** riscv_dct4_instance_f32 *S, float32_t *pState, float32_t *pInlineBuffer)

Processing function for the floating-point DCT4/IDCT4.

Return none

Parameters

- [in] S: points to an instance of the floating-point DCT4/IDCT4 structure
- [in] pState: points to state buffer
- [inout] pInlineBuffer: points to the in-place input and output buffer

riscv_status **riscv_dct4_init_f32** (riscv_dct4_instance_f32 *S, riscv_rfft_instance_f32 *S_RFFT, riscv_cfft_radix4_instance_f32 *S_CFFT, uint16_t N, uint16_t Nby2, float32_t normalize)

Initialization function for the floating-point DCT4/IDCT4.

DCT Size	Normalizing factor value
2048	0.03125
512	0.0625
128	0.125

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : N is not a supported transform length

Normalizing factor The normalizing factor is $\sqrt{2/N}$, which depends on the size of transform N. Floating-point normalizing factors are mentioned in the table below for different DCT sizes:

Parameters

- [inout] S: points to an instance of floating-point DCT4/IDCT4 structure
- [in] S_RFFT: points to an instance of floating-point RFFT/RIFFT structure
- [in] S_CFFT: points to an instance of floating-point CFFT/CIFFT structure
- [in] N: length of the DCT4
- [in] Nby2: half of the length of the DCT4
- [in] normalize: normalizing factor.

riscv_status **riscv_dct4_init_q15** (riscv_dct4_instance_q15 *S, riscv_rfft_instance_q15 *S_RFFT, riscv_cfft_radix4_instance_q15 *S_CFFT, uint16_t N, uint16_t Nby2, q15_t normalize)

Initialization function for the Q15 DCT4/IDCT4.

DCT Size	Normalizing factor value (hexadecimal)
2048	0x400
512	0x800
128	0x1000

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : N is not a supported transform length

Normalizing factor The normalizing factor is $\sqrt{2/N}$, which depends on the size of transform N. Normalizing factors in 1.15 format are mentioned in the table below for different DCT sizes:

Parameters

- [inout] S: points to an instance of Q15 DCT4/IDCT4 structure
- [in] S_RFFT: points to an instance of Q15 RFFT/RIFFT structure
- [in] S_CFFT: points to an instance of Q15 CFFT/CIFFT structure
- [in] N: length of the DCT4
- [in] Nby2: half of the length of the DCT4
- [in] normalize: normalizing factor

riscv_status **riscv_dct4_init_q31** (riscv_dct4_instance_q31 *S, riscv_rfft_instance_q31 *S_RFFT, riscv_cfft_radix4_instance_q31 *S_CFFT, uint16_t N, uint16_t Nby2, q31_t normalize)

Initialization function for the Q31 DCT4/IDCT4.

DCT Size	Normalizing factor value (hexadecimal)
2048	0x4000000
512	0x8000000
128	0x10000000

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : N is not a supported transform length

Normalizing factor: The normalizing factor is $\sqrt{2/N}$, which depends on the size of transform N. Normalizing factors in 1.31 format are mentioned in the table below for different DCT sizes:

Parameters

- [inout] S: points to an instance of Q31 DCT4/IDCT4 structure.

- [in] `S_RFFT`: points to an instance of Q31 RFFT/RIFFT structure
- [in] `S_CFFT`: points to an instance of Q31 CFFT/CIFFT structure
- [in] `N`: length of the DCT4.
- [in] `Nby2`: half of the length of the DCT4.
- [in] `normalize`: normalizing factor.

void **riscv_dct4_q15** (**const** riscv_dct4_instance_q15 *S, q15_t *pState, q15_t *pInlineBuffer)
Processing function for the Q15 DCT4/IDCT4.

DCT Size	Input format	Output format	Number of bits to upscale
2048	1.15	11.5	10
512	1.15	9.7	8
128	1.15	7.9	6

Return none

Input an output formats Internally inputs are downscaled in the RFFT process function to avoid overflows. Number of bits downscaled, depends on the size of the transform. The input and output formats for different DCT sizes and number of bits to upscale are mentioned in the table below:

Parameters

- [in] `S`: points to an instance of the Q15 DCT4 structure.
- [in] `pState`: points to state buffer.
- [inout] `pInlineBuffer`: points to the in-place input and output buffer.

void **riscv_dct4_q31** (**const** riscv_dct4_instance_q31 *S, q31_t *pState, q31_t *pInlineBuffer)
Processing function for the Q31 DCT4/IDCT4.

DCT Size	Input format	Output format	Number of bits to upscale
2048	2.30	12.20	11
512	2.30	10.22	9
128	2.30	8.24	7

Return none

Input an output formats Input samples need to be downscaled by 1 bit to avoid saturations in the Q31 DCT process, as the conversion from DCT2 to DCT4 involves one subtraction. Internally inputs are downscaled in the RFFT process function to avoid overflows. Number of bits downscaled, depends on the size of the transform. The input and output formats for different DCT sizes and number of bits to upscale are mentioned in the table below:

Parameters

- [in] `S`: points to an instance of the Q31 DCT4 structure.
- [in] `pState`: points to state buffer.
- [inout] `pInlineBuffer`: points to the in-place input and output buffer.

Real FFT Functions

Real FFT Tables

```

const float32_t realCoefA[8192]
const float32_t realCoefB[8192]
const q31_t realCoefAQ31[8192]
const q31_t realCoefBQ31[8192]
const q15_t __ALIGNED(4)
group RealFFT_Table

```

Functions

```
const q15_t __ALIGNED(4)
```

Weights Table.

Q15 table for reciprocal.

end of DCT4_IDCT4_Table group

Generation fixed-point realCoefAQ15 array in Q15 format:

n = 4096

Convert to fixed point Q15 format round(pATable[i] * pow(2, 15))

Generation of real_CoefB array:

n = 4096

Convert to fixed point Q15 format round(pBTable[i] * pow(2, 15))

Weights tables are generated using the formula :

C command to generate the table

where N is the Number of weights to be calculated and c is $\pi / (2 * N)$

Converted the output to q15 format by multiplying with 2^{31} and saturated if required.

In the tables below the real and imaginary values are placed alternatively, hence the array length is $2 * N$.

cosFactor tables are generated using the formula :

C command to generate the table

where N is the number of factors to generate and c is $\pi / (2 * N)$

Then converted to q15 format by multiplying with 2^{31} and saturated if required.

Variables

```

const float32_t realCoefA[8192]
    Generation of realCoefA array:
    n = 4096
const float32_t realCoefB[8192]

```

Generation of realCoefB array:

n = 4096

const q31_t **realCoefAQ31**[8192]

Generation fixed-point realCoefAQ31 array in Q31 format:

n = 4096

Convert to fixed point Q31 format round(pATable[i] * pow(2, 31))

const q31_t **realCoefBQ31**[8192]

Generation of realCoefBQ31 array:

n = 4096

Convert to fixed point Q31 format round(pBTable[i] * pow(2, 31))

group **RealFFT**

The NMSIS DSP library includes specialized algorithms for computing the FFT of real data sequences. The FFT is defined over complex data but in many applications the input is real. Real FFT algorithms take advantage of the symmetry properties of the FFT and have a speed advantage over complex algorithms of the same length.

The Fast RFFT algorithm relays on the mixed radix CFFT that save processor usage.

The real length N forward FFT of a sequence is computed using the steps shown below.

The real sequence is initially treated as if it were complex to perform a CFFT. Later, a processing stage reshapes the data to obtain half of the frequency spectrum in complex format. Except the first complex number that contains the two real numbers $X[0]$ and $X[N/2]$ all the data is complex. In other words, the first complex sample contains two real values packed.

The input for the inverse RFFT should keep the same format as the output of the forward RFFT. A first processing stage pre-process the data to later perform an inverse CFFT.

The algorithms for floating-point, Q15, and Q31 data are slightly different and we describe each algorithm in turn.

Floating-point The main functions are `riscv_rfft_fast_f32()` and `riscv_rfft_fast_init_f32()`. The older functions `riscv_rfft_f32()` and `riscv_rfft_init_f32()` have been deprecated but are still documented.

The FFT of a real N -point sequence has even symmetry in the frequency domain. The second half of the data equals the conjugate of the first half flipped in frequency. Looking at the data, we see that we can uniquely represent the FFT using only $N/2$ complex numbers. These are packed into the output array in alternating real and imaginary components:

$$X = \{ \text{real}[0], \text{imag}[0], \text{real}[1], \text{imag}[1], \text{real}[2], \text{imag}[2] \dots \text{real}[(N/2)-1], \text{imag}[(N/2)-1] \}$$

It happens that the first complex number ($\text{real}[0], \text{imag}[0]$) is actually all real. $\text{real}[0]$ represents the DC offset, and $\text{imag}[0]$ should be 0. ($\text{real}[1], \text{imag}[1]$) is the fundamental frequency, ($\text{real}[2], \text{imag}[2]$) is the first harmonic and so on.

The real FFT functions pack the frequency domain data in this fashion. The forward transform outputs the data in this form and the inverse transform expects input data in this form. The function always performs the needed bitreversal so that the input and output data is always in normal order. The functions support lengths of [32, 64, 128, ..., 4096] samples.

Q15 and Q31 The real algorithms are defined in a similar manner and utilize $N/2$ complex transforms behind the scenes.

The complex transforms used internally include scaling to prevent fixed-point overflows. The overall scaling equals $1/(\text{fftLen}/2)$. Due to the use of complex transform internally, the source buffer is modified by the rfft.

A separate instance structure must be defined for each transform used but twiddle factor and bit reversal tables can be reused.

There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Sets the values of the internal structure fields.
- Initializes twiddle factor table and bit reversal table pointers.

- Initializes the internal complex FFT data structure.

Use of the initialization function is optional **except for MVE versions where it is mandatory**. If you don't use the initialization functions, then the structures should be initialized with code similar to the one below: where `fftLenReal` is the length of the real transform; `fftLenBy2` length of the internal complex transform (`fftLenReal/2`). `ifftFlagR` Selects forward (=0) or inverse (=1) transform. `bitReverseFlagR` Selects bit reversed output (=0) or normal order output (=1). `twiddleCoefRModifier` stride modifier for the twiddle factor table. The value is based on the FFT length; `pTwiddleAReal` points to the A array of twiddle coefficients; `pTwiddleBReal` points to the B array of twiddle coefficients; `pCfft` points to the CFFT Instance structure. The CFFT structure must also be initialized.

Note that with MVE versions you can't initialize instance structures directly and **must use the initialization function**.

Functions

void **riscv_rfft_f32** (const riscv_rfft_instance_f32 *S, float32_t *pSrc, float32_t *pDst)

Processing function for the floating-point RFFT/RIFFT. Source buffer is modified by this function.

Return none

For the RIFFT, the source buffer must at least have length `fftLenReal + 2`. The last two elements must be equal to what would be generated by the RFFT: (`pSrc[0] - pSrc[1]`) and 0.0f

Parameters

- [in] S: points to an instance of the floating-point RFFT/RIFFT structure
- [in] pSrc: points to the input buffer
- [out] pDst: points to the output buffer

void **riscv_rfft_fast_f32** (const riscv_rfft_fast_instance_f32 *S, float32_t *p, float32_t *pOut, uint8_t *ifftFlag*)

Processing function for the floating-point real FFT.

Return none

Parameters

- [in] S: points to an `riscv_rfft_fast_instance_f32` structure
- [in] p: points to input buffer (Source buffer is modified by this function.)
- [in] pOut: points to output buffer
- [in] *ifftFlag*:
 - value = 0: RFFT
 - value = 1: RIFFT

void **riscv_rfft_fast_f64** (riscv_rfft_fast_instance_f64 *S, float64_t *p, float64_t *pOut, uint8_t *ifftFlag*)

Processing function for the Double Precision floating-point real FFT.

Return none

Parameters

- [in] S: points to an `riscv_rfft_fast_instance_f64` structure

- [in] p: points to input buffer (Source buffer is modified by this function.)
- [in] pOut: points to output buffer
- [in] ifftFlag:
 - value = 0: RFFT
 - value = 1: RIFFT

static riscv_status **riscv_rfft_32_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
 Initialization function for the 32pt floating-point real FFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an riscv_rfft_fast_instance_f32 structure

static riscv_status **riscv_rfft_64_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
 Initialization function for the 64pt floating-point real FFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an riscv_rfft_fast_instance_f32 structure

static riscv_status **riscv_rfft_128_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
 Initialization function for the 128pt floating-point real FFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an riscv_rfft_fast_instance_f32 structure

static riscv_status **riscv_rfft_256_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
 Initialization function for the 256pt floating-point real FFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an riscv_rfft_fast_instance_f32 structure

static riscv_status **riscv_rfft_512_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
 Initialization function for the 512pt floating-point real FFT.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f32` structure

static riscv_status **riscv_rfft_1024_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
Initialization function for the 1024pt floating-point real FFT.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f32` structure

static riscv_status **riscv_rfft_2048_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
Initialization function for the 2048pt floating-point real FFT.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f32` structure

static riscv_status **riscv_rfft_4096_fast_init_f32** (riscv_rfft_fast_instance_f32 *S)
Initialization function for the 4096pt floating-point real FFT.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f32` structure

riscv_status **riscv_rfft_fast_init_f32** (riscv_rfft_fast_instance_f32 *S, uint16_t *fftLen*)
Initialization function for the floating-point real FFT.

Return execution status

- RISCV_MATH_SUCCESS : Operation successful
- RISCV_MATH_ARGUMENT_ERROR : *fftLen* is not a supported length

Description The parameter *fftLen* specifies the length of RFFT/CIFFT process. Supported FFT Lengths are 32, 64, 128, 256, 512, 1024, 2048, 4096.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f32` structure
- [in] `fftLen`: length of the Real Sequence

static `riscv_status riscv_rfft_32_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)
 Initialization function for the 32pt double precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_64_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)
 Initialization function for the 64pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_128_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)
 Initialization function for the 128pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_256_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)
 Initialization function for the 256pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- [inout] S: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_512_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)
 Initialization function for the 512pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful

- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- `[inout] S`: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_1024_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)

Initialization function for the 1024pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- `[inout] S`: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_2048_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)

Initialization function for the 2048pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- `[inout] S`: points to an `riscv_rfft_fast_instance_f64` structure

static `riscv_status riscv_rfft_4096_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`)

Initialization function for the 4096pt Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : an error is detected

Parameters

- `[inout] S`: points to an `riscv_rfft_fast_instance_f64` structure

`riscv_status riscv_rfft_fast_init_f64` (`riscv_rfft_fast_instance_f64 *S`, `uint16_t fftLen`)

Initialization function for the Double Precision floating-point real FFT.

Return execution status

- `RISCV_MATH_SUCCESS` : Operation successful
- `RISCV_MATH_ARGUMENT_ERROR` : `fftLen` is not a supported length

Description The parameter `fftLen` specifies the length of RFFT/CIFFT process. Supported FFT Lengths are 32, 64, 128, 256, 512, 1024, 2048, 4096.

This Function also initializes Twiddle factor table pointer and Bit reversal table pointer.

Parameters

- `[inout] S`: points to an `riscv_rfft_fast_instance_f64` structure
- `[in] fftLen`: length of the Real Sequence

```
riscv_status riscv_rfft_init_f32 (riscv_rfft_instance_f32 *S, riscv_cfft_radix4_instance_f32
                                *S_CFFT, uint32_t fftLenReal, uint32_t ifftFlagR, uint32_t
                                bitReverseFlag)
```

Initialization function for the floating-point RFFT/RIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : *fftLenReal* is not a supported length

Description The parameter *fftLenReal* specifies length of RFFT/RIFFT Process. Supported FFT Lengths are 128, 512, 2048.

The parameter *ifftFlagR* controls whether a forward or inverse transform is computed. Set(=1) *ifftFlagR* to calculate RIFFT, otherwise RFFT is calculated.

The parameter *bitReverseFlag* controls whether output is in normal order or bit reversed order. Set(=1) *bitReverseFlag* for output to be in normal order otherwise output is in bit reversed order.

This function also initializes Twiddle factor table.

Parameters

- [inout] *S*: points to an instance of the floating-point RFFT/RIFFT structure
- [inout] *S_CFFT*: points to an instance of the floating-point CFFT/CIFFT structure
- [in] *fftLenReal*: length of the FFT.
- [in] *ifftFlagR*: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] *bitReverseFlag*: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

```
riscv_status riscv_rfft_init_q15 (riscv_rfft_instance_q15 *S, uint32_t fftLenReal, uint32_t ifft-
                                FlagR, uint32_t bitReverseFlag)
```

Initialization function for the Q15 RFFT/RIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : *fftLenReal* is not a supported length

Details The parameter *fftLenReal* specifies length of RFFT/RIFFT Process. Supported FFT Lengths are 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192.

The parameter *ifftFlagR* controls whether a forward or inverse transform is computed. Set(=1) *ifftFlagR* to calculate RIFFT, otherwise RFFT is calculated.

The parameter *bitReverseFlag* controls whether output is in normal order or bit reversed order. Set(=1) *bitReverseFlag* for output to be in normal order otherwise output is in bit reversed order.

This function also initializes Twiddle factor table.

Parameters

- [inout] *S*: points to an instance of the Q15 RFFT/RIFFT structure

- [in] `fftLenReal`: length of the FFT
- [in] `ifftFlagR`: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] `bitReverseFlag`: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

riscv_status **riscv_rfft_init_q31** (riscv_rfft_instance_q31 *S, uint32_t *fftLenReal*, uint32_t *ifftFlagR*, uint32_t *bitReverseFlag*)

Initialization function for the Q31 RFFT/RIFFT.

Return execution status

- RISC_V_MATH_SUCCESS : Operation successful
- RISC_V_MATH_ARGUMENT_ERROR : `fftLenReal` is not a supported length

Details The parameter `fftLenReal` specifies length of RFFT/RIFFT Process. Supported FFT Lengths are 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192.

The parameter `ifftFlagR` controls whether a forward or inverse transform is computed. Set(=1) `ifftFlagR` to calculate RIFFT, otherwise RFFT is calculated.

The parameter `bitReverseFlag` controls whether output is in normal order or bit reversed order. Set(=1) `bitReverseFlag` for output to be in normal order otherwise output is in bit reversed order.

This function also initializes Twiddle factor table.

Parameters

- [inout] `S`: points to an instance of the Q31 RFFT/RIFFT structure
- [in] `fftLenReal`: length of the FFT
- [in] `ifftFlagR`: flag that selects transform direction
 - value = 0: forward transform
 - value = 1: inverse transform
- [in] `bitReverseFlag`: flag that enables / disables bit reversal of output
 - value = 0: disables bit reversal of output
 - value = 1: enables bit reversal of output

void **riscv_rfft_q15** (const riscv_rfft_instance_q15 *S, q15_t *pSrc, q15_t *pDst)

Processing function for the Q15 RFFT/RIFFT.

Return none

Input an output formats Internally input is downscaled by 2 for every stage to avoid saturations inside CFFT/CIFFT process. Hence the output format is different for different RFFT sizes. The input and output formats for different RFFT sizes and number of bits to upscale are mentioned in the tables below for RFFT and RIFFT:

RFFT Size	Input Format	Output Format	Number of bits to upscale
32	1.15	5.11	4
64	1.15	6.10	5
128	1.15	7.9	6
256	1.15	8.8	7
512	1.15	9.7	8
1024	1.15	10.6	9
2048	1.15	11.5	10
4096	1.15	12.4	11
8192	1.15	13.3	12

RFFT Size	Input Format	Output Format	Number of bits to upscale
32	1.15	5.11	0
64	1.15	6.10	0
128	1.15	7.9	0
256	1.15	8.8	0
512	1.15	9.7	0
1024	1.15	10.6	0
2048	1.15	11.5	0
4096	1.15	12.4	0
8192	1.15	13.3	0

If the input buffer is of length N , the output buffer must have length $2*N$. The input buffer is modified by this function.

For the RIFFT, the source buffer must at least have length $\text{fftLenReal} + 2$. The last two elements must be equal to what would be generated by the RFFT: $(\text{pSrc}[0] - \text{pSrc}[1]) \gg 1$ and 0

Parameters

- [in] *S*: points to an instance of the Q15 RFFT/RIFFT structure
- [in] *pSrc*: points to input buffer (Source buffer is modified by this function.)
- [out] *pDst*: points to output buffer

void **riscv_rfft_q31** (const riscv_rfft_instance_q31 **S*, q31_t **pSrc*, q31_t **pDst*)

Processing function for the Q31 RFFT/RIFFT.

Return none

Input an output formats Internally input is downscaled by 2 for every stage to avoid saturations inside CFFT/CIFFT process. Hence the output format is different for different RFFT sizes. The input and output formats for different RFFT sizes and number of bits to upscale are mentioned in the tables below for RFFT and RIFFT:

RFFT Size	Input Format	Output Format	Number of bits to upscale
32	1.31	5.27	4
64	1.31	6.26	5
128	1.31	7.25	6
256	1.31	8.24	7
512	1.31	9.23	8
1024	1.31	10.22	9
2048	1.31	11.21	10
4096	1.31	21.20	11
8192	1.31	13.19	12

RFFT Size	Input Format	Output Format	Number of bits to upscale
32	1.31	5.27	0
64	1.31	6.26	0
128	1.31	7.25	0
256	1.31	8.24	0
512	1.31	9.23	0
1024	1.31	10.22	0
2048	1.31	11.21	0
4096	1.31	12.20	0
8192	1.31	13.19	0

If the input buffer is of length N , the output buffer must have length $2*N$. The input buffer is modified by this function.

For the RIFFT, the source buffer must at least have length $\text{fftLenReal} + 2$. The last two elements must be equal to what would be generated by the RFFT: $(\text{pSrc}[0] - \text{pSrc}[1]) \gg 1$ and 0

Parameters

- [in] *S*: points to an instance of the Q31 RFFT/RIFFT structure
- [in] *pSrc*: points to input buffer (Source buffer is modified by this function)
- [out] *pDst*: points to output buffer

group **PID**

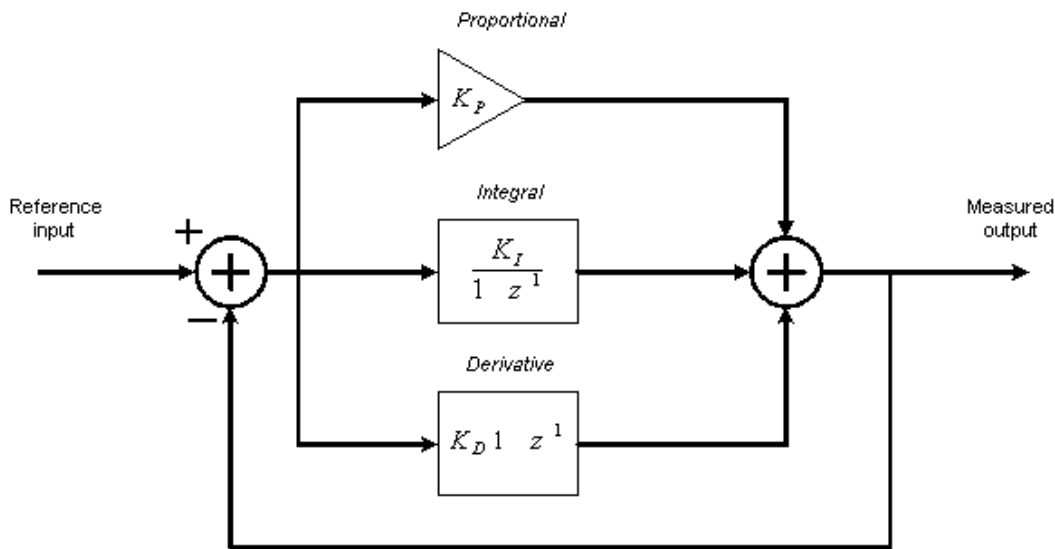

end of SinCos group

A Proportional Integral Derivative (PID) controller is a generic feedback control loop mechanism widely used in industrial control systems. A PID controller is the most commonly used type of feedback controller.

This set of functions implements (PID) controllers for Q15, Q31, and floating-point data types. The functions operate on a single sample of data and each call to the function returns a single processed value. *S* points to an instance of the PID control data structure. *in* is the input sample value. The functions return the output value.

Algorithm:

where K_p is proportional constant, K_i is Integral constant and K_d is Derivative constant

The PID controller calculates an “error” value as the difference between the measured output and the reference input. The controller attempts to minimize the error by adjusting the process control inputs. The proportional value determines the reaction to the current error, the integral value determines the reaction based on the sum of recent errors, and the derivative value determines the reaction based on the rate at which the error has been changing.

Instance Structure The Gains A_0 , A_1 , A_2 and state variables for a PID controller are stored together in an instance data structure. A separate instance structure must be defined for each PID Controller. There are separate instance structure declarations for each of the 3 supported data types.

Reset Functions There is also an associated reset function for each data type which clears the state array.

Initialization Functions There is also an associated initialization function for each data type. The initialization function performs the following operations:

- Initializes the Gains A_0 , A_1 , A_2 from K_p , K_i , K_d gains.

- Zeros out the values in the state buffer.

Instance structure cannot be placed into a const data section and it is recommended to use the initialization function.

Fixed-Point Behavior Care must be taken when using the fixed-point versions of the PID Controller functions. In particular, the overflow and saturation behavior of the accumulator used in each function must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

__STATIC_FORCEINLINE float32_t riscv_pid_f32(riscv_pid_instance_f32 * S, float32_t in)
Process function for the floating-point PID Control.

Return processed output sample.

Parameters

- [inout] S: is an instance of the floating-point PID Control structure
- [in] in: input sample to process

__STATIC_FORCEINLINE q31_t riscv_pid_q31(riscv_pid_instance_q31 * S, q31_t in)
Process function for the Q31 PID Control.

Return processed output sample.

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The accumulator has a 2.62 format and maintains full precision of the intermediate multiplication results but provides only a single guard bit. Thus, if the accumulator result overflows it wraps around rather than clip. In order to avoid overflows completely the input signal must be scaled down by 2 bits as there are four additions. After all multiply-accumulates are performed, the 2.62 accumulator is truncated to 1.32 format and then saturated to 1.31 format.

Parameters

- [inout] S: points to an instance of the Q31 PID Control structure
- [in] in: input sample to process

__STATIC_FORCEINLINE q15_t riscv_pid_q15(riscv_pid_instance_q15 * S, q15_t in)
Process function for the Q15 PID Control.

Return processed output sample.

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. Both Gains and state variables are represented in 1.15 format and multiplications yield a 2.30 result. The 2.30 intermediate results are accumulated in a 64-bit accumulator in 34.30 format. There is no risk of internal overflow with this approach and the full precision of intermediate multiplications is preserved. After all additions have been performed, the accumulator is truncated to 34.15 format by discarding low 15 bits. Lastly, the accumulator is saturated to yield a result in 1.15 format.

Parameters

- [inout] S: points to an instance of the Q15 PID Control structure
- [in] in: input sample to process

void riscv_pid_init_f32(riscv_pid_instance_f32 *S, int32_t resetStateFlag)
Initialization function for the floating-point PID Control.

Return none

Details The `resetStateFlag` specifies whether to set state to zero or not. The function computes the structure fields: A0, A1 A2 using the proportional gain(K_p), integral gain(K_i) and derivative gain(K_d) also sets the state variables to all zeros.

Parameters

- [inout] `S`: points to an instance of the PID structure
- [in] `resetStateFlag`:
 - value = 0: no change in state
 - value = 1: reset state

void **riscv_pid_init_q15** (riscv_pid_instance_q15 **S*, int32_t *resetStateFlag*)
Initialization function for the Q15 PID Control.

Return none

Details The `resetStateFlag` specifies whether to set state to zero or not. The function computes the structure fields: A0, A1 A2 using the proportional gain(K_p), integral gain(K_i) and derivative gain(K_d) also sets the state variables to all zeros.

Parameters

- [inout] `S`: points to an instance of the Q15 PID structure
- [in] `resetStateFlag`:
 - value = 0: no change in state
 - value = 1: reset state

void **riscv_pid_init_q31** (riscv_pid_instance_q31 **S*, int32_t *resetStateFlag*)
Initialization function for the Q31 PID Control.

Return none

Details The `resetStateFlag` specifies whether to set state to zero or not. The function computes the structure fields: A0, A1 A2 using the proportional gain(K_p), integral gain(K_i) and derivative gain(K_d) also sets the state variables to all zeros.

Parameters

- [inout] `S`: points to an instance of the Q31 PID structure
- [in] `resetStateFlag`:
 - value = 0: no change in state
 - value = 1: reset state

void **riscv_pid_reset_f32** (riscv_pid_instance_f32 **S*)
Reset function for the floating-point PID Control.

Return none

Details The function resets the state buffer to zeros.

Parameters

- [inout] `S`: points to an instance of the floating-point PID structure

void **riscv_pid_reset_q15** (riscv_pid_instance_q15 *S)
Reset function for the Q15 PID Control.

Return none

Details The function resets the state buffer to zeros.

Parameters

- [inout] S: points to an instance of the Q15 PID structure

void **riscv_pid_reset_q31** (riscv_pid_instance_q31 *S)
Reset function for the Q31 PID Control.

Return none

Details The function resets the state buffer to zeros.

Parameters

- [inout] S: points to an instance of the Q31 PID structure

Vector Clarke Transform

```
__STATIC_FORCEINLINE void riscv_clarke_f32(float32_t Ia, float32_t Ib, float32_t * pIalpha,
```

```
__STATIC_FORCEINLINE void riscv_clarke_q31(q31_t Ia, q31_t Ib, q31_t * pIalpha, q31_t * pIb,
```

group **clarke**

end of Inverse park group

Forward Clarke transform converts the instantaneous stator phases into a two-coordinate time invariant vector. Generally the Clarke transform uses three-phase currents I_a , I_b and I_c to calculate currents in the two-phase orthogonal stator axis I_{α} and I_{β} . When I_{α} is superposed with I_a as shown in the figure below and $I_a + I_b + I_c = 0$, in this condition I_{α} and I_{β} can be calculated using only I_a and

Ib.

The function operates on a single sample of data and each call to the function returns the processed output. The library provides separate functions for Q31 and floating-point data types.

Algorithm

where I_a and I_b are the instantaneous stator phases and pI_{α} and pI_{β} are the two coordinates

$$pI_{\alpha} = I_a$$

$$pI_{\beta} = (1/\sqrt{3}) I_a + (2/\sqrt{3}) I_b$$

of time invariant vector.

Fixed-Point Behavior Care must be taken when using the Q31 version of the Clarke transform. In particular, the overflow and saturation behavior of the accumulator used must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

`__STATIC_FORCEINLINE void riscv_clarke_f32(float32_t Ia, float32_t Ib, float32_t * pIa)`
Floating-point Clarke transform.

Return none

Parameters

- [in] I_a : input three-phase coordinate a
- [in] I_b : input three-phase coordinate b
- [out] pI_{α} : points to output two-phase orthogonal vector axis alpha

- [out] pIbeta: points to output two-phase orthogonal vector axis beta

__STATIC_FORCEINLINE void riscv_clarke_q31(q31_t Ia, q31_t Ib, q31_t * pIalpha, q31_t * pIbeta)
Clarke transform for Q31 version.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 32-bit accumulator. The accumulator maintains 1.31 format by truncating lower 31 bits of the intermediate multiplication in 2.62 format. There is saturation on the addition, hence there is no risk of overflow.

Parameters

- [in] Ia: input three-phase coordinate a
- [in] Ib: input three-phase coordinate b
- [out] pIalpha: points to output two-phase orthogonal vector axis alpha
- [out] pIbeta: points to output two-phase orthogonal vector axis beta

Vector Inverse Clarke Transform

__STATIC_FORCEINLINE void riscv_inv_clarke_f32(float32_t Ialpha, float32_t Ibeta, float32_t * pIa, float32_t * pIb)
__STATIC_FORCEINLINE void riscv_inv_clarke_q31(q31_t Ialpha, q31_t Ibeta, q31_t * pIa, q31_t * pIb)

group inv_clarke
end of clarke group

Inverse Clarke transform converts the two-coordinate time invariant vector into instantaneous stator phases.

The function operates on a single sample of data and each call to the function returns the processed output. The library provides separate functions for Q31 and floating-point data types.

Algorithm

where pIa and pIb are the instantaneous stator phases and Ialpha and Ibeta are the two coordinates

$$pIa = Ialpha$$

$$pIb = (-1/2) Ialpha + (\sqrt{3}/2) Ibeta$$

of time invariant vector.

Fixed-Point Behavior Care must be taken when using the Q31 version of the Clarke transform. In particular, the overflow and saturation behavior of the accumulator used must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

__STATIC_FORCEINLINE void riscv_inv_clarke_f32(float32_t Ialpha, float32_t Ibeta, float32_t * pIa, float32_t * pIb)
Floating-point Inverse Clarke transform.

Return none

Parameters

- [in] Ialpha: input two-phase orthogonal vector axis alpha
- [in] Ibeta: input two-phase orthogonal vector axis beta

- [out] pIa: points to output three-phase coordinate a
- [out] pIb: points to output three-phase coordinate b

__STATIC_FORCEINLINE void riscv_inv_clarke_q31(q31_t Ialpha, q31_t Ibeta, q31_t * pIa,
Inverse Clarke transform for Q31 version.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 32-bit accumulator. The accumulator maintains 1.31 format by truncating lower 31 bits of the intermediate multiplication in 2.62 format. There is saturation on the subtraction, hence there is no risk of overflow.

Parameters

- [in] Ialpha: input two-phase orthogonal vector axis alpha
- [in] Ibeta: input two-phase orthogonal vector axis beta
- [out] pIa: points to output three-phase coordinate a
- [out] pIb: points to output three-phase coordinate b

Vector Park Transform

__STATIC_FORCEINLINE void riscv_park_f32(float32_t Ialpha, float32_t Ibeta, float32_t * pId,

__STATIC_FORCEINLINE void riscv_park_q31(q31_t Ialpha, q31_t Ibeta, q31_t * pId, q31_t * pIq,

group park

end of PID group

Forward Park transform converts the input two-coordinate vector to flux and torque components. The Park transform can be used to realize the transformation of the Ialpha and the Ibeta currents from the stationary to the moving reference frame and control the spatial relationship between the stator vector current and rotor flux vector. If we consider the d axis aligned with the rotor flux, the diagram below shows the current vector and the relationship from the two reference frames: The function operates on a single sample of data and each call to the function returns the processed output. The library provides separate functions for Q31 and floating-point

data types.

Algorithm

where Ialpha and Ibeta are the stator vector components, pId and pIq are rotor vector components and cosVal and sinVal are the cosine and sine values of theta (rotor flux position).

$$\begin{aligned} pId &= Ialpha * cosVal + Ibeta * sinVal \\ pIq &= - Ialpha sinVal + Ibeta * cosVal \end{aligned}$$

Fixed-Point Behavior Care must be taken when using the Q31 version of the Park transform. In particular, the overflow and saturation behavior of the accumulator used must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

`__STATIC_FORCEINLINE void riscv_park_f32(float32_t Ialpha, float32_t Ibeta, float32_t * pId, float32_t * pIq, float32_t sinVal, float32_t cosVal)`
Floating-point Park transform.

The function implements the forward Park transform.

Return none

Parameters

- [in] Ialpha: input two-phase vector coordinate alpha
- [in] Ibeta: input two-phase vector coordinate beta
- [out] pId: points to output rotor reference frame d
- [out] pIq: points to output rotor reference frame q
- [in] sinVal: sine value of rotation angle theta
- [in] cosVal: cosine value of rotation angle theta

`__STATIC_FORCEINLINE void riscv_park_q31(q31_t Ialpha, q31_t Ibeta, q31_t * pId, q31_t * pIq, q31_t sinVal, q31_t cosVal)`
Park transform for Q31 version.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 32-bit accumulator. The accumulator maintains 1.31 format by truncating lower 31 bits of the intermediate multiplication in 2.62 format. There is saturation on the addition and subtraction, hence there is no risk of overflow.

Parameters

- [in] Ialpha: input two-phase vector coordinate alpha
- [in] Ibeta: input two-phase vector coordinate beta
- [out] pId: points to output rotor reference frame d
- [out] pIq: points to output rotor reference frame q
- [in] sinVal: sine value of rotation angle theta
- [in] cosVal: cosine value of rotation angle theta

Vector Inverse Park transform

`__STATIC_FORCEINLINE void riscv_inv_park_f32(float32_t Id, float32_t Iq, float32_t * pIalpha, float32_t * pIbeta, float32_t sinVal, float32_t cosVal)`
`__STATIC_FORCEINLINE void riscv_inv_park_q31(q31_t Id, q31_t Iq, q31_t * pIalpha, q31_t * pIbeta, q31_t sinVal, q31_t cosVal)`

group **inv_park**
end of park group

Inverse Park transform converts the input flux and torque components to two-coordinate vector.

The function operates on a single sample of data and each call to the function returns the processed output. The library provides separate functions for Q31 and floating-point data types.

Algorithm

where `pIalpha` and `pIbeta` are the stator vector components, `Id` and `Iq` are rotor vector components and `cosVal` and `sinVal` are the cosine and sine values of theta (rotor flux position).

$$\begin{aligned} pIalpha &= Id * \cosVal - Iq * \sinVal \\ pIbeta &= Id * \sinVal + Iq * \cosVal \end{aligned}$$

Fixed-Point Behavior Care must be taken when using the Q31 version of the Park transform. In particular, the overflow and saturation behavior of the accumulator used must be considered. Refer to the function specific documentation below for usage guidelines.

Functions

__STATIC_FORCEINLINE void riscv_inv_park_f32(float32_t Id, float32_t Iq, float32_t * pIalpha, float32_t * pIbeta, float32_t sinVal, float32_t cosVal)
Floating-point Inverse Park transform.

Return none

Parameters

- [in] `Id`: input coordinate of rotor reference frame d
- [in] `Iq`: input coordinate of rotor reference frame q
- [out] `pIalpha`: points to output two-phase orthogonal vector axis alpha
- [out] `pIbeta`: points to output two-phase orthogonal vector axis beta
- [in] `sinVal`: sine value of rotation angle theta
- [in] `cosVal`: cosine value of rotation angle theta

__STATIC_FORCEINLINE void riscv_inv_park_q31(q31_t Id, q31_t Iq, q31_t * pIalpha, q31_t * pIbeta, q31_t sinVal, q31_t cosVal)
Inverse Park transform for Q31 version.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 32-bit accumulator. The accumulator maintains 1.31 format by truncating lower 31 bits of the intermediate multiplication in 2.62 format. There is saturation on the addition, hence there is no risk of overflow.

Parameters

- [in] `Id`: input coordinate of rotor reference frame d
- [in] `Iq`: input coordinate of rotor reference frame q
- [out] `pIalpha`: points to output two-phase orthogonal vector axis alpha
- [out] `pIbeta`: points to output two-phase orthogonal vector axis beta

- [in] `sinVal`: sine value of rotation angle `theta`
- [in] `cosVal`: cosine value of rotation angle `theta`

Sine Cosine

void **riscv_sin_cos_f32** (float32_t *theta*, float32_t **pSinVal*, float32_t **pCosVal*)

void **riscv_sin_cos_q31** (q31_t *theta*, q31_t **pSinVal*, q31_t **pCosVal*)

group SinCos

Computes the trigonometric sine and cosine values using a combination of table lookup and linear interpolation. There are separate functions for Q31 and floating-point data types. The input to the floating-point version is in degrees while the fixed-point Q31 have a scaled input with the range [-1 0.9999] mapping to [-180 +180] degrees.

The floating point function also allows values that are out of the usual range. When this happens, the function will take extra time to adjust the input value to the range of [-180 180].

The result is accurate to 5 digits after the decimal point.

The implementation is based on table lookup using 360 values together with linear interpolation. The steps used are:

1. Calculation of the nearest integer table index.
2. Compute the fractional portion (fract) of the input.
3. Fetch the value corresponding to `index` from sine table to `y0` and also value from `index+1` to `y1`.
4. Sine value is computed as `*psinVal = y0 + (fract * (y1 - y0))`.
5. Fetch the value corresponding to `index` from cosine table to `y0` and also value from `index+1` to `y1`.
6. Cosine value is computed as `*pcosVal = y0 + (fract * (y1 - y0))`.

Functions

void **riscv_sin_cos_f32** (float32_t *theta*, float32_t **pSinVal*, float32_t **pCosVal*)

Floating-point `sin_cos` function.

Return none

Parameters

- [in] `theta`: input value in degrees
- [out] `pSinVal`: points to the processed sine output.
- [out] `pCosVal`: points to the processed cos output.
- [in] `theta`: input value in degrees
- [out] `pSinVal`: points to processed sine output
- [out] `pCosVal`: points to processed cosine output

void **riscv_sin_cos_q31** (q31_t *theta*, q31_t **pSinVal*, q31_t **pCosVal*)

Q31 `sin_cos` function.

The Q31 input value is in the range [-1 0.999999] and is mapped to a degree value in the range [-180 179].

Return none

Parameters

- [in] theta: scaled input value in degrees
- [out] pSinVal: points to the processed sine output.
- [out] pCosVal: points to the processed cosine output.
- [in] theta: scaled input value in degrees
- [out] pSinVal: points to processed sine output
- [out] pCosVal: points to processed cosine output

3.3.8 Statistics Functions

Maximum

void **riscv_max_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult, uint32_t *pIndex)

void **riscv_max_no_idx_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)

void **riscv_max_q15** (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult, uint32_t *pIndex)

void **riscv_max_q31** (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult, uint32_t *pIndex)

void **riscv_max_q7** (const q7_t *pSrc, uint32_t blockSize, q7_t *pResult, uint32_t *pIndex)

group **Max**

Computes the maximum value of an array of data. The function returns both the maximum value and its position within the array. There are separate functions for floating-point, Q31, Q15, and Q7 data types.

Functions

void **riscv_max_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult, uint32_t *pIndex)

Maximum value of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: maximum value returned here
- [out] pIndex: index of maximum value returned here

void **riscv_max_no_idx_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)

Maximum value of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector

- [out] `pResult`: maximum value returned here

void **riscv_max_q15** (**const** q15_t **pSrc*, uint32_t *blockSize*, q15_t **pResult*, uint32_t **pIndex*)
Maximum value of a Q15 vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: maximum value returned here
- [out] `pIndex`: index of maximum value returned here

void **riscv_max_q31** (**const** q31_t **pSrc*, uint32_t *blockSize*, q31_t **pResult*, uint32_t **pIndex*)
Maximum value of a Q31 vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: maximum value returned here
- [out] `pIndex`: index of maximum value returned here

void **riscv_max_q7** (**const** q7_t **pSrc*, uint32_t *blockSize*, q7_t **pResult*, uint32_t **pIndex*)
Maximum value of a Q7 vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: maximum value returned here
- [out] `pIndex`: index of maximum value returned here

Mean

void **riscv_mean_f32** (**const** float32_t **pSrc*, uint32_t *blockSize*, float32_t **pResult*)

void **riscv_mean_q15** (**const** q15_t **pSrc*, uint32_t *blockSize*, q15_t **pResult*)

void **riscv_mean_q31** (**const** q31_t **pSrc*, uint32_t *blockSize*, q31_t **pResult*)

void **riscv_mean_q7** (**const** q7_t **pSrc*, uint32_t *blockSize*, q7_t **pResult*)

group mean

Functions

void **riscv_mean_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)

Mean value of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to the input vector.
- [in] blockSize: number of samples in input vector.
- [out] pResult: mean value returned here.

void **riscv_mean_q15** (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult)

Mean value of a Q15 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. The input is represented in 1.15 format and is accumulated in a 32-bit accumulator in 17.15 format. There is no risk of internal overflow with this approach, and the full precision of intermediate result is preserved. Finally, the accumulator is truncated to yield a result of 1.15 format.

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: mean value returned here

void **riscv_mean_q31** (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult)

Mean value of a Q31 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. The input is represented in 1.31 format and is accumulated in a 64-bit accumulator in 33.31 format. There is no risk of internal overflow with this approach, and the full precision of intermediate result is preserved. Finally, the accumulator is truncated to yield a result of 1.31 format.

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: mean value returned here

void **riscv_mean_q7** (const q7_t *pSrc, uint32_t blockSize, q7_t *pResult)

Mean value of a Q7 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. The input is represented in 1.7 format and is accumulated in a 32-bit accumulator in 25.7 format. There is no risk of internal overflow with this approach, and the full precision of intermediate result is preserved. Finally, the accumulator is truncated to yield a result of 1.7 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: mean value returned here

Minimum

void **riscv_min_f32** (**const** float32_t **pSrc*, uint32_t *blockSize*, float32_t **pResult*, uint32_t **pIndex*)

void **riscv_min_q15** (**const** q15_t **pSrc*, uint32_t *blockSize*, q15_t **pResult*, uint32_t **pIndex*)

void **riscv_min_q31** (**const** q31_t **pSrc*, uint32_t *blockSize*, q31_t **pResult*, uint32_t **pIndex*)

void **riscv_min_q7** (**const** q7_t **pSrc*, uint32_t *blockSize*, q7_t **pResult*, uint32_t **pIndex*)

group **Min**

Computes the minimum value of an array of data. The function returns both the minimum value and its position within the array. There are separate functions for floating-point, Q31, Q15, and Q7 data types.

Functions

void **riscv_min_f32** (**const** float32_t **pSrc*, uint32_t *blockSize*, float32_t **pResult*, uint32_t **pIndex*)

Minimum value of a floating-point vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: minimum value returned here
- [out] `pIndex`: index of minimum value returned here

void **riscv_min_q15** (**const** q15_t **pSrc*, uint32_t *blockSize*, q15_t **pResult*, uint32_t **pIndex*)

Minimum value of a Q15 vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: minimum value returned here
- [out] `pIndex`: index of minimum value returned here

void **riscv_min_q31** (**const** q31_t **pSrc*, uint32_t *blockSize*, q31_t **pResult*, uint32_t **pIndex*)

Minimum value of a Q31 vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector

- [in] blockSize: number of samples in input vector
- [out] pResult: minimum value returned here
- [out] pIndex: index of minimum value returned here

void **riscv_min_q7** (const q7_t *pSrc, uint32_t blockSize, q7_t *pResult, uint32_t *pIndex)
Minimum value of a Q7 vector.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: minimum value returned here
- [out] pIndex: index of minimum value returned here

Power

void **riscv_power_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)

void **riscv_power_q15** (const q15_t *pSrc, uint32_t blockSize, q63_t *pResult)

void **riscv_power_q31** (const q31_t *pSrc, uint32_t blockSize, q63_t *pResult)

void **riscv_power_q7** (const q7_t *pSrc, uint32_t blockSize, q31_t *pResult)

group power

Calculates the sum of the squares of the elements in the input vector. The underlying algorithm is used:

There are separate functions for floating point, Q31, Q15, and Q7 data types.

Since the result is not divided by the length, those functions are in fact computing something which is more an energy than a power.

Functions

void **riscv_power_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)
Sum of the squares of the elements of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: sum of the squares value returned here

void **riscv_power_q15** (const q15_t *pSrc, uint32_t blockSize, q63_t *pResult)
Sum of the squares of the elements of a Q15 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. The input is represented in 1.15 format. Intermediate multiplication yields a 2.30 format, and this result is added without saturation to a 64-bit accumulator in 34.30 format. With 33 guard bits in the accumulator, there is no risk of overflow, and the full precision of the intermediate multiplication is preserved. Finally, the return result is in 34.30 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: sum of the squares value returned here

void **riscv_power_q31** (const q31_t **pSrc*, uint32_t *blockSize*, q63_t **pResult*)
Sum of the squares of the elements of a Q31 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. The input is represented in 1.31 format. Intermediate multiplication yields a 2.62 format, and this result is truncated to 2.48 format by discarding the lower 14 bits. The 2.48 result is then added without saturation to a 64-bit accumulator in 16.48 format. With 15 guard bits in the accumulator, there is no risk of overflow, and the full precision of the intermediate multiplication is preserved. Finally, the return result is in 16.48 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: sum of the squares value returned here

void **riscv_power_q7** (const q7_t **pSrc*, uint32_t *blockSize*, q31_t **pResult*)
Sum of the squares of the elements of a Q7 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 32-bit internal accumulator. The input is represented in 1.7 format. Intermediate multiplication yields a 2.14 format, and this result is added without saturation to an accumulator in 18.14 format. With 17 guard bits in the accumulator, there is no risk of overflow, and the full precision of the intermediate multiplication is preserved. Finally, the return result is in 18.14 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: sum of the squares value returned here

Root mean square (RMS)

void **riscv_rms_f32** (const float32_t **pSrc*, uint32_t *blockSize*, float32_t **pResult*)

void **riscv_rms_q15** (const q15_t **pSrc*, uint32_t *blockSize*, q15_t **pResult*)

void **riscv_rms_q31** (const q31_t **pSrc*, uint32_t *blockSize*, q31_t **pResult*)

group **RMS**

Calculates the Root Mean Square of the elements in the input vector. The underlying algorithm is used:

There are separate functions for floating point, Q31, and Q15 data types.

Functions

void **riscv_rms_f32** (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)

Root Mean Square of the elements of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: root mean square value returned here

void **riscv_rms_q15** (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult)

Root Mean Square of the elements of a Q15 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. The input is represented in 1.15 format. Intermediate multiplication yields a 2.30 format, and this result is added without saturation to a 64-bit accumulator in 34.30 format. With 33 guard bits in the accumulator, there is no risk of overflow, and the full precision of the intermediate multiplication is preserved. Finally, the 34.30 result is truncated to 34.15 format by discarding the lower 15 bits, and then saturated to yield a result in 1.15 format.

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: root mean square value returned here

void **riscv_rms_q31** (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult)

Root Mean Square of the elements of a Q31 vector.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The input is represented in 1.31 format, and intermediate multiplication yields a 2.62 format. The accumulator maintains full precision of the intermediate multiplication results, but provides only a single guard bit. There is no saturation on intermediate additions. If the accumulator overflows, it wraps around and distorts the result. In order to avoid overflows completely, the input signal must be scaled down by $\log_2(\text{blockSize})$ bits, as a total of blockSize additions are performed internally. Finally, the 2.62 accumulator is right shifted by 31 bits to yield a 1.31 format value.

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: root mean square value returned here

Standard deviation

```
void riscv_std_f32 (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)
```

```
void riscv_std_q15 (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult)
```

```
void riscv_std_q31 (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult)
```

group STD

Calculates the standard deviation of the elements in the input vector.

The float implementation is relying on `riscv_var_f32` which is using a two-pass algorithm to avoid problem of numerical instabilities and cancellation errors.

Fixed point versions are using the standard textbook algorithm since the fixed point numerical behavior is different from the float one.

Algorithm for fixed point versions is summarized below:

There are separate functions for floating point, Q31, and Q15 data types.

Functions

```
void riscv_std_f32 (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)
```

Standard deviation of the elements of a floating-point vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: standard deviation value returned here

```
void riscv_std_q15 (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult)
```

Standard deviation of the elements of a Q15 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. The input is represented in 1.15 format. Intermediate multiplication yields a 2.30 format, and this result is added without saturation to a 64-bit accumulator in 34.30 format. With 33 guard bits in the accumulator, there is no risk of overflow, and the full precision of the intermediate multiplication is preserved. Finally, the 34.30 result is truncated to 34.15 format by discarding the lower 15 bits, and then saturated to yield a result in 1.15 format.

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: standard deviation value returned here

```
void riscv_std_q31 (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult)
```

Standard deviation of the elements of a Q31 vector.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The input is represented in 1.31 format, which is then downshifted by 8 bits which yields 1.23, and intermediate multiplication yields a 2.46 format. The accumulator maintains full precision of the intermediate multiplication results, but provides only a 16 guard bits. There is no saturation on intermediate additions. If the accumulator overflows it wraps around and distorts the result. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{blockSize})-8$ bits, as a total of `blockSize` additions are performed internally. After division, internal variables should be Q18.46. Finally, the 18.46 accumulator is right shifted by 15 bits to yield a 1.31 format value.

Parameters

- [in] `pSrc`: points to the input vector.
- [in] `blockSize`: number of samples in input vector.
- [out] `pResult`: standard deviation value returned here.

Variance

```
void riscv_var_f32 (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)
```

```
void riscv_var_q15 (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult)
```

```
void riscv_var_q31 (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult)
```

group variance

Calculates the variance of the elements in the input vector. The underlying algorithm used is the direct method sometimes referred to as the two-pass method:

There are separate functions for floating point, Q31, and Q15 data types.

Functions

```
void riscv_var_f32 (const float32_t *pSrc, uint32_t blockSize, float32_t *pResult)
```

Variance of the elements of a floating-point vector.

Return none

Parameters

- [in] `pSrc`: points to the input vector
- [in] `blockSize`: number of samples in input vector
- [out] `pResult`: variance value returned here

```
void riscv_var_q15 (const q15_t *pSrc, uint32_t blockSize, q15_t *pResult)
```

Variance of the elements of a Q15 vector.

Return none

Scaling and Overflow Behavior The function is implemented using a 64-bit internal accumulator. The input is represented in 1.15 format. Intermediate multiplication yields a 2.30 format, and this result is added without saturation to a 64-bit accumulator in 34.30 format. With 33 guard bits in the accumulator, there is no risk of overflow, and the full precision of the intermediate multiplication is preserved. Finally, the 34.30 result is truncated to 34.15 format by discarding the lower 15 bits, and then saturated to yield a result in 1.15 format.

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: variance value returned here

void **riscv_var_q31** (const q31_t *pSrc, uint32_t blockSize, q31_t *pResult)

Variance of the elements of a Q31 vector.

Return none

Scaling and Overflow Behavior The function is implemented using an internal 64-bit accumulator. The input is represented in 1.31 format, which is then downshifted by 8 bits which yields 1.23, and intermediate multiplication yields a 2.46 format. The accumulator maintains full precision of the intermediate multiplication results, and as a consequence has only 16 guard bits. There is no saturation on intermediate additions. If the accumulator overflows it wraps around and distorts the result. In order to avoid overflows completely the input signal must be scaled down by $\log_2(\text{blockSize}) - 8$ bits, as a total of blockSize additions are performed internally. After division, internal variables should be Q18.46. Finally, the 18.46 accumulator is right shifted by 15 bits to yield a 1.31 format value.

Parameters

- [in] pSrc: points to the input vector
- [in] blockSize: number of samples in input vector
- [out] pResult: variance value returned here

group **groupStats**

3.3.9 Support Functions

Vector Copy

void **riscv_copy_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

void **riscv_copy_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_copy_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)

void **riscv_copy_q7** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)

group **copy**

Copies sample by sample from source vector to destination vector.

There are separate functions for floating point, Q31, Q15, and Q7 data types.

Functions

void **riscv_copy_f32** (const float32_t *pSrc, float32_t *pDst, uint32_t blockSize)

Copies the elements of a floating-point vector.

Return none

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] blockSize: number of samples in each vector

void **riscv_copy_q15** (const q15_t *pSrc, q15_t *pDst, uint32_t blockSize)
Copies the elements of a Q15 vector.

Return none

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] blockSize: number of samples in each vector

void **riscv_copy_q31** (const q31_t *pSrc, q31_t *pDst, uint32_t blockSize)
Copies the elements of a Q31 vector.

Return none

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] blockSize: number of samples in each vector

void **riscv_copy_q7** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)
Copies the elements of a Q7 vector.

Return none

Parameters

- [in] pSrc: points to input vector
- [out] pDst: points to output vector
- [in] blockSize: number of samples in each vector

Vector Fill

void **riscv_fill_f32** (float32_t value, float32_t *pDst, uint32_t blockSize)

void **riscv_fill_q15** (q15_t value, q15_t *pDst, uint32_t blockSize)

void **riscv_fill_q31** (q31_t value, q31_t *pDst, uint32_t blockSize)

void **riscv_fill_q7** (q7_t value, q7_t *pDst, uint32_t blockSize)

group Fill

Fills the destination vector with a constant value.

There are separate functions for floating point, Q31, Q15, and Q7 data types.

Functions

void **riscv_fill_f32** (float32_t value, float32_t *pDst, uint32_t blockSize)

Fills a constant value into a floating-point vector.

Return none

Parameters

- [in] `value`: input value to be filled
- [out] `pDst`: points to output vector
- [in] `blockSize`: number of samples in each vector

void **riscv_fill_q15** (*q15_t value, q15_t *pDst, uint32_t blockSize*)
Fills a constant value into a Q15 vector.

Return none

Parameters

- [in] `value`: input value to be filled
- [out] `pDst`: points to output vector
- [in] `blockSize`: number of samples in each vector

void **riscv_fill_q31** (*q31_t value, q31_t *pDst, uint32_t blockSize*)
Fills a constant value into a Q31 vector.

Return none

Parameters

- [in] `value`: input value to be filled
- [out] `pDst`: points to output vector
- [in] `blockSize`: number of samples in each vector

void **riscv_fill_q7** (*q7_t value, q7_t *pDst, uint32_t blockSize*)
Fills a constant value into a Q7 vector.

Return none

Parameters

- [in] `value`: input value to be filled
- [out] `pDst`: points to output vector
- [in] `blockSize`: number of samples in each vector

Convert 32-bit floating point value

void **riscv_float_to_q15** (**const** *float32_t *pSrc, q15_t *pDst, uint32_t blockSize*)

void **riscv_float_to_q31** (**const** *float32_t *pSrc, q31_t *pDst, uint32_t blockSize*)

void **riscv_float_to_q7** (**const** *float32_t *pSrc, q7_t *pDst, uint32_t blockSize*)

group **float_to_x**

Functions

void **riscv_float_to_q15** (const float32_t *pSrc, q15_t *pDst, uint32_t blockSize)

Converts the elements of the floating-point vector to Q15 vector.

Return none

Details The equation used for the conversion process is:

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] are saturated.

Note In order to apply rounding, the library should be rebuilt with the ROUNDING macro defined in the preprocessor section of project options.

Parameters

- [in] pSrc: points to the floating-point input vector
- [out] pDst: points to the Q15 output vector
- [in] blockSize: number of samples in each vector

void **riscv_float_to_q31** (const float32_t *pSrc, q31_t *pDst, uint32_t blockSize)

Converts the elements of the floating-point vector to Q31 vector.

Return none

Details The equation used for the conversion process is:

Scaling and Overflow Behavior The function uses saturating arithmetic. Results outside of the allowable Q31 range [0x80000000 0x7FFFFFFF] are saturated.

Note In order to apply rounding, the library should be rebuilt with the ROUNDING macro defined in the preprocessor section of project options.

Parameters

- [in] pSrc: points to the floating-point input vector
- [out] pDst: points to the Q31 output vector
- [in] blockSize: number of samples in each vector

void **riscv_float_to_q7** (const float32_t *pSrc, q7_t *pDst, uint32_t blockSize)

Converts the elements of the floating-point vector to Q7 vector.

Return none.

Description:

The equation used for the conversion process is:

Scaling and Overflow Behavior:

The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] will be saturated.

Note In order to apply rounding, the library should be rebuilt with the ROUNDING macro defined in the preprocessor section of project options.

Parameters

- [in] *pSrc: points to the floating-point input vector

- [out] *pDst: points to the Q7 output vector
- [in] blockSize: length of the input vector

Convert 16-bit Integer value

void **riscv_q15_to_float** (const q15_t *pSrc, float32_t *pDst, uint32_t blockSize)

void **riscv_q15_to_q31** (const q15_t *pSrc, q31_t *pDst, uint32_t blockSize)

void **riscv_q15_to_q7** (const q15_t *pSrc, q7_t *pDst, uint32_t blockSize)

group **q15_to_x**

Functions

void **riscv_q15_to_float** (const q15_t *pSrc, float32_t *pDst, uint32_t blockSize)

Converts the elements of the Q15 vector to floating-point vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q15 input vector
- [out] pDst: points to the floating-point output vector
- [in] blockSize: number of samples in each vector

void **riscv_q15_to_q31** (const q15_t *pSrc, q31_t *pDst, uint32_t blockSize)

Converts the elements of the Q15 vector to Q31 vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q15 input vector
- [out] pDst: points to the Q31 output vector
- [in] blockSize: number of samples in each vector

void **riscv_q15_to_q7** (const q15_t *pSrc, q7_t *pDst, uint32_t blockSize)

Converts the elements of the Q15 vector to Q7 vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q15 input vector
- [out] pDst: points to the Q7 output vector
- [in] blockSize: number of samples in each vector

Convert 32-bit Integer value

void **riscv_q31_to_float** (const q31_t *pSrc, float32_t *pDst, uint32_t blockSize)

void **riscv_q31_to_q15** (const q31_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_q31_to_q7** (const q31_t *pSrc, q7_t *pDst, uint32_t blockSize)

group **q31_to_x**

Functions

void **riscv_q31_to_float** (const q31_t *pSrc, float32_t *pDst, uint32_t blockSize)

Converts the elements of the Q31 vector to floating-point vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q31 input vector
- [out] pDst: points to the floating-point output vector
- [in] blockSize: number of samples in each vector

void **riscv_q31_to_q15** (const q31_t *pSrc, q15_t *pDst, uint32_t blockSize)

Converts the elements of the Q31 vector to Q15 vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q31 input vector
- [out] pDst: points to the Q15 output vector
- [in] blockSize: number of samples in each vector

void **riscv_q31_to_q7** (const q31_t *pSrc, q7_t *pDst, uint32_t blockSize)

Converts the elements of the Q31 vector to Q7 vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q31 input vector
- [out] pDst: points to the Q7 output vector
- [in] blockSize: number of samples in each vector

Convert 8-bit Integer value

void **riscv_q7_to_float** (const q7_t *pSrc, float32_t *pDst, uint32_t blockSize)

void **riscv_q7_to_q15** (const q7_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_q7_to_q31** (const q7_t *pSrc, q31_t *pDst, uint32_t blockSize)

group **q7_to_x**

Functions

void **riscv_q7_to_float** (const q7_t *pSrc, float32_t *pDst, uint32_t blockSize)

Converts the elements of the Q7 vector to floating-point vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q7 input vector
- [out] pDst: points to the floating-point output vector
- [in] blockSize: number of samples in each vector

void **riscv_q7_to_q15** (const q7_t *pSrc, q15_t *pDst, uint32_t blockSize)

Converts the elements of the Q7 vector to Q15 vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q7 input vector
- [out] pDst: points to the Q15 output vector
- [in] blockSize: number of samples in each vector

void **riscv_q7_to_q31** (const q7_t *pSrc, q31_t *pDst, uint32_t blockSize)

Converts the elements of the Q7 vector to Q31 vector.

Return none

Details The equation used for the conversion process is:

Parameters

- [in] pSrc: points to the Q7 input vector
- [out] pDst: points to the Q31 output vector
- [in] blockSize: number of samples in each vector

group **groupSupport**

3.3.10 Interpolation Functions

Linear Interpolation

`float32_t riscv_linear_interp_f32 (riscv_linear_interp_instance_f32 *S, float32_t x)`

`q31_t riscv_linear_interp_q31 (q31_t *pYData, q31_t x, uint32_t nValues)`

`q15_t riscv_linear_interp_q15 (q15_t *pYData, q31_t x, uint32_t nValues)`

`q7_t riscv_linear_interp_q7 (q7_t *pYData, q31_t x, uint32_t nValues)`

group **LinearInterpolate**

Linear interpolation is a method of curve fitting using linear polynomials. Linear interpolation works by effectively drawing a straight line between two neighboring samples and returning the appropriate point along that line

end of SplineInterpolate group

A Linear Interpolate function calculates an output value(y), for the input(x) using linear interpolation of the input values x0, x1(nearest input values) and the output values y0 and y1(nearest output values)

Algorithm:

This set of functions implements Linear interpolation process for Q7, Q15, Q31, and floating-point data types. The functions operate on a single sample of data and each call to the function returns a single processed

value. *S* points to an instance of the Linear Interpolate function data structure. *x* is the input sample value. The functions returns the output value.

if *x* is outside of the table boundary, Linear interpolation returns first value of the table if *x* is below input range and returns last value of table if *x* is above range.

Functions

`float32_t riscv_linear_interp_f32 (riscv_linear_interp_instance_f32 *S, float32_t x)`

Process function for the floating-point Linear Interpolation Function.

Return *y* processed output sample.

Parameters

- [inout] *S*: is an instance of the floating-point Linear Interpolation structure
- [in] *x*: input sample to process

`q31_t riscv_linear_interp_q31 (q31_t *pYData, q31_t x, uint32_t nValues)`

Process function for the Q31 Linear Interpolation Function.

Return *y* processed output sample.

Input sample *x* is in 12.20 format which contains 12 bits for table index and 20 bits for fractional part. This function can support maximum of table size 2^{12} .

Parameters

- [in] *pYData*: pointer to Q31 Linear Interpolation table
- [in] *x*: input sample to process
- [in] *nValues*: number of table values

`q15_t riscv_linear_interp_q15 (q15_t *pYData, q31_t x, uint32_t nValues)`

Process function for the Q15 Linear Interpolation Function.

Return *y* processed output sample.

Input sample *x* is in 12.20 format which contains 12 bits for table index and 20 bits for fractional part. This function can support maximum of table size 2^{12} .

Parameters

- [in] *pYData*: pointer to Q15 Linear Interpolation table
- [in] *x*: input sample to process
- [in] *nValues*: number of table values

`q7_t riscv_linear_interp_q7 (q7_t *pYData, q31_t x, uint32_t nValues)`

Process function for the Q7 Linear Interpolation Function.

Return *y* processed output sample.

Input sample *x* is in 12.20 format which contains 12 bits for table index and 20 bits for fractional part. This function can support maximum of table size 2^{12} .

Parameters

- [in] *pYData*: pointer to Q7 Linear Interpolation table

- [in] *x*: input sample to process
- [in] *nValues*: number of table values

Bilinear Interpolation

`float32_t riscv_bilinear_interp_f32 (const riscv_bilinear_interp_instance_f32 *S, float32_t X, float32_t Y)`

`q31_t riscv_bilinear_interp_q31 (riscv_bilinear_interp_instance_q31 *S, q31_t X, q31_t Y)`

`q15_t riscv_bilinear_interp_q15 (riscv_bilinear_interp_instance_q15 *S, q31_t X, q31_t Y)`

`q7_t riscv_bilinear_interp_q7 (riscv_bilinear_interp_instance_q7 *S, q31_t X, q31_t Y)`

group **BilinearInterpolate**

Bilinear interpolation is an extension of linear interpolation applied to a two dimensional grid. The underlying function $f(x, y)$ is sampled on a regular grid and the interpolation process determines values between the grid points. Bilinear interpolation is equivalent to two step linear interpolation, first in the x-dimension and then in the y-dimension. Bilinear interpolation is often used in image processing to rescale images. The NMSIS DSP library provides bilinear interpolation functions for Q7, Q15, Q31, and floating-point data types.

Algorithm end of LinearInterpolate group

The instance structure used by the bilinear interpolation functions describes a two dimensional data table. For floating-point, the instance structure is defined as:

where `numRows` specifies the number of rows in the table; `numCols` specifies the number of columns in the table; and `pData` points to an array of size `numRows*numCols` values. The data table `pTable` is organized in row order and the supplied data values fall on integer indexes. That is, table element (x,y) is located at `pTable[x + y*numCols]` where `x` and `y` are integers.

Let (x, y) specify the desired interpolation point. Then define:

The interpolated output point is computed as: Note that the coordinates (x, y) contain integer and fractional components. The integer components specify which portion of the table to use while the fractional components control the interpolation processor.

if (x,y) are outside of the table boundary, Bilinear interpolation returns zero output.

Functions

`float32_t riscv_bilinear_interp_f32 (const riscv_bilinear_interp_instance_f32 *S, float32_t X, float32_t Y)`

Floating-point bilinear interpolation.

Return out interpolated value.

Parameters

- [inout] *S*: points to an instance of the interpolation structure.
- [in] *X*: interpolation coordinate.
- [in] *Y*: interpolation coordinate.

`q31_t riscv_bilinear_interp_q31 (riscv_bilinear_interp_instance_q31 *S, q31_t X, q31_t Y)`
Q31 bilinear interpolation.

Return out interpolated value.

Parameters

- [inout] S: points to an instance of the interpolation structure.
- [in] X: interpolation coordinate in 12.20 format.
- [in] Y: interpolation coordinate in 12.20 format.

q15_t **riscv_bilinear_interp_q15** (riscv_bilinear_interp_instance_q15 *S, q31_t X, q31_t Y)
Q15 bilinear interpolation.

Return out interpolated value.

Parameters

- [inout] S: points to an instance of the interpolation structure.
- [in] X: interpolation coordinate in 12.20 format.
- [in] Y: interpolation coordinate in 12.20 format.

q7_t **riscv_bilinear_interp_q7** (riscv_bilinear_interp_instance_q7 *S, q31_t X, q31_t Y)
Q7 bilinear interpolation.

Return out interpolated value.

Parameters

- [inout] S: points to an instance of the interpolation structure.
- [in] X: interpolation coordinate in 12.20 format.
- [in] Y: interpolation coordinate in 12.20 format.

group **Interpolation**

These functions perform 1- and 2-dimensional interpolation of data. Linear interpolation is used for 1-dimensional data and bilinear interpolation is used for 2-dimensional data.

3.3.11 Examples

Class Marks Example*group* **ClassMarks**

Refer riscv_class_marks_example_f32.c

Description:

Demonstrates the use the Maximum, Minimum, Mean, Standard Deviation, Variance and Matrix functions to calculate statistical values of marks obtained in a class.

Note This example also demonstrates the usage of static initialization.

Variables Description:

- testMarks_f32 points to the marks scored by 20 students in 4 subjects
- max_marks Maximum of all marks
- min_marks Minimum of all marks
- mean Mean of all marks

- `var` Variance of the marks
- `std` Standard deviation of the marks
- `numStudents` Total number of students in the class

NMSIS DSP Software Library Functions Used:

- `riscv_mat_init_f32()`
- `riscv_mat_mult_f32()`
- `riscv_max_f32()`
- `riscv_min_f32()`
- `riscv_mean_f32()`
- `riscv_std_f32()`
- `riscv_var_f32()`

Convolution Example

group **ConvolutionExample**

Refer `riscv_convolution_example_f32.c`

Description:

Demonstrates the convolution theorem with the use of the Complex FFT, Complex-by-Complex Multiplication, and Support Functions.

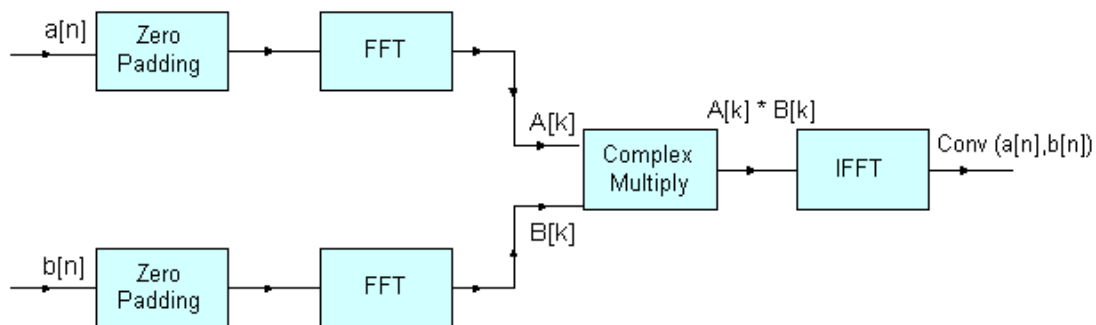

Algorithm:

The convolution theorem states that convolution in the time domain corresponds to multiplication in the frequency domain. Therefore, the Fourier transform of the convolution of two signals is equal to the product of their individual Fourier transforms. The Fourier transform of a signal can be evaluated efficiently using the Fast Fourier Transform (FFT).

Two input signals, $a[n]$ and $b[n]$, with lengths n_1 and n_2 respectively, are zero padded so that their lengths become N , which is greater than or equal to $(n_1 + n_2 - 1)$ and is a power of 4 as FFT implementation is radix-4. The convolution of $a[n]$ and $b[n]$ is obtained by taking the FFT of the input signals, multiplying the Fourier transforms of the two signals, and taking the inverse FFT of the multiplied result.

This is denoted by the following equations: where $A[k]$ and $B[k]$ are the N -point FFTs of the signals $a[n]$ and $b[n]$ respectively. The length of the convolved signal is $(n_1 + n_2 - 1)$.

Block Diagram:

Variables Description:

- `testInputA_f32` points to the first input sequence
- `srcALen` length of the first input sequence
- `testInputB_f32` points to the second input sequence
- `srcBLen` length of the second input sequence
- `outLen` length of convolution output sequence, $(srcALen + srcBLen - 1)$
- `AxB` points to the output array where the product of individual FFTs of inputs is stored.

NMSIS DSP Software Library Functions Used:

- `riscv_fill_f32()`
- `riscv_copy_f32()`
- `riscv_cfft_radix4_init_f32()`
- `riscv_cfft_radix4_f32()`
- `riscv_cmplx_mult_cmplx_f32()`

Dot Product Example

group **DotproductExample**

Refer `riscv_dotproduct_example_f32.c`

Description:

Demonstrates the use of the Multiply and Add functions to perform the dot product. The dot product of two vectors is obtained by multiplying corresponding elements and summing the products.

Algorithm:

The two input vectors A and B with length n , are multiplied element-by-element and then added to obtain dot product.

This is denoted by the following equation:

Block Diagram:**Variables Description:**

- `srcA_buf_f32` points to first input vector
- `srcB_buf_f32` points to second input vector

- testOutput stores dot product of the two input vectors.

NMSIS DSP Software Library Functions Used:

- riscv_mult_f32()
- riscv_add_f32()

Frequency Bin Example

group **FrequencyBin**

Refer riscv_fft_bin_example_f32.c

Description

Demonstrates the calculation of the maximum energy bin in the frequency domain of the input signal with the use of Complex FFT, Complex Magnitude, and Maximum functions.

Algorithm:

The input test signal contains a 10 kHz signal with uniformly distributed white noise. Calculating the FFT of the input signal will give us the maximum energy of the bin corresponding to the input frequency of 10 kHz.

Block Diagram:

The figure below shows the time domain signal of 10 kHz signal with uniformly distributed white noise, and the next figure shows the input in the frequency domain. The bin with maximum energy corresponds to 10 kHz signal.

Variables Description:

- `testInput_f32_10khz` points to the input data
- `testOutput` points to the output data
- `fftSize` length of FFT
- `ifftFlag` flag for the selection of CFFT/CIFFT
- `doBitReverse` Flag for selection of normal order or bit reversed order
- `refIndex` reference index value at which maximum energy of bin occurs
- `testIndex` calculated index value at which maximum energy of bin occurs

NMSIS DSP Software Library Functions Used:

- `riscv_cfft_f32()`
- `riscv_cmplx_mag_f32()`
- `riscv_max_f32()`

FIR Lowpass Filter Example

group **FIRLPF**

Refer `riscv_fir_example_f32.c`

Description:

Removes high frequency signal components from the input using an FIR lowpass filter. The example demonstrates how to configure an FIR filter and then pass data through it in a block-by-block fashion.

Algorithm:

The input signal is a sum of two sine waves: 1 kHz and 15 kHz. This is processed by an FIR lowpass filter with cutoff frequency 6 kHz. The lowpass filter eliminates the 15 kHz signal leaving only the 1 kHz sine wave at the output.

The lowpass filter was designed using MATLAB with a sample rate of 48 kHz and a length of 29 points. The MATLAB code to generate the filter coefficients is shown below: The first argument is the “order” of the filter and is always one less than the desired length. The second argument is the normalized cutoff frequency. This is in the range 0 (DC) to 1.0 (Nyquist). A 6 kHz cutoff with a Nyquist frequency of 24 kHz lies at a normalized frequency of $6/24 = 0.25$. The NMSIS FIR filter function requires the coefficients to be in time reversed order. The resulting filter coefficients are shown below. Note that the filter is symmetric (a property of linear phase FIR filters) and the point of symmetry is sample 14. Thus the filter will have a delay of 14 samples for all frequencies.

The frequency response of the filter is shown next. The passband gain of the filter is 1.0 and it reaches 0.5 at the cutoff frequency 6 kHz.

The input signal is shown below. The left hand side shows the signal in the time domain while the right hand side is a frequency domain representation. The two sine wave components can be clearly seen.

The output of the filter is shown below. The 15 kHz component has been eliminated.

Variables Description:

- `testInput_f32_1kHz_15kHz` points to the input data
- `refOutput` points to the reference output data
- `testOutput` points to the test output data

- `firStateF32` points to state buffer
- `firCoeffs32` points to coefficient buffer
- `blockSize` number of samples processed at a time
- `numBlocks` number of frames

NMSIS DSP Software Library Functions Used:

- `riscv_fir_init_f32()`
- `riscv_fir_f32()`

Graphic Audio Equalizer Example

group **GEQ5Band**

Refer `riscv_graphic_equalizer_example_q31.c`

Description:

This example demonstrates how a 5-band graphic equalizer can be constructed using the Biquad cascade functions. A graphic equalizer is used in audio applications to vary the tonal quality of the audio.

Block Diagram:

The design is based on a cascade of 5 filter sections. Each filter section is 4th order and consists of a cascade of two Biquads. Each filter has a nominal gain of 0 dB (1.0 in linear units) and boosts or cuts signals within a specific frequency range. The edge frequencies between the 5 bands are 100, 500, 2000, and 6000 Hz. Each band has an adjustable boost or cut in the range of +/- 9 dB. For example, the band that extends from 500 to 2000 Hz has the response shown below:

With 1 dB steps, each filter has a total of 19 different settings. The filter coefficients for all possible 19 settings were precomputed in MATLAB and stored in a table. With 5 different tables, there are a total of $5 \times 19 = 95$ different 4th order filters. All 95 responses are shown below:

Each 4th order filter has 10 coefficients for a grand total of 950 different filter coefficients that must be tabulated. The input and output data is in Q31 format. For better noise performance, the two low frequency bands are implemented using the high precision 32x64-bit Biquad filters. The remaining 3 high frequency bands use standard 32x32-bit Biquad filters. The input signal used in the example is a logarithmic chirp.

The array `bandGains` specifies the gain in dB to apply in each band. For example, if `bandGains={0, -3, 6, 4, -6}`; then the output signal will be:

Note The output chirp signal follows the gain or boost of each band.

Variables Description:

- `testInput_f32` points to the input data

- `testRefOutput_f32` points to the reference output data
- `testOutput` points to the test output data
- `inputQ31` temporary input buffer
- `outputQ31` temporary output buffer
- `biquadStateBand1Q31` points to state buffer for band1
- `biquadStateBand2Q31` points to state buffer for band2
- `biquadStateBand3Q31` points to state buffer for band3
- `biquadStateBand4Q31` points to state buffer for band4
- `biquadStateBand5Q31` points to state buffer for band5
- `coeffTable` points to coefficient buffer for all bands
- `gainDB` gain buffer which has gains applied for all the bands

NMSIS DSP Software Library Functions Used:

Linear Interpolate Example

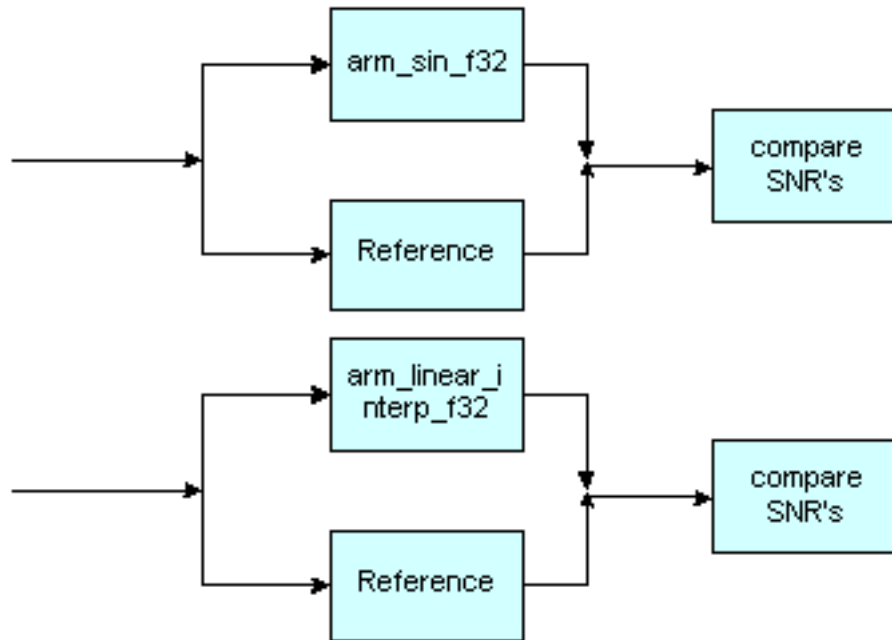

group **LinearInterpExample**

NMSIS DSP Software Library Linear Interpolate Example

Description This example demonstrates usage of linear interpolate modules and fast math modules. Method 1 uses fast math sine function to calculate sine values using cubic interpolation and method 2 uses linear interpolation function and results are compared to reference output. Example shows linear interpolation function can be used to get higher precision compared to fast math sin calculation.

Refer `riscv_linear_interp_example_f32.c`

Block Diagram:

**Variables Description:**

- testInputSin_f32 points to the input values for sine calculation
- testRefSinOutput32_f32 points to the reference values caculated from sin() matlab function
- testOutput points to output buffer calculation from cubic interpolation
- testLinIntOutput points to output buffer calculation from linear interpolation
- snr1 Signal to noise ratio for reference and cubic interpolation output
- snr2 Signal to noise ratio for reference and linear interpolation output

NMSIS DSP Software Library Functions Used:

- riscv_sin_f32()
- riscv_linear_interp_f32()

Matrix Example

group **MatrixExample**

Refer riscv_matrix_example_f32.c

Description:

Demonstrates the use of Matrix Transpose, Matrix Mulplication, and Matrix Inverse functions to apply least squares fitting to input data. Least squares fitting is the procedure for finding the best-fitting curve that minimizes the sum of the squares of the offsets (least square error) from a given set of data.

Algorithm:

The linear combination of parameters considered is as follows:

$A * X = B$, where X is the unknown value and can be estimated from A & B.

The least squares estimate X is given by the following equation:

$$X = \text{Inverse}(A^T * A) * A^T * B$$

Block Diagram:

Variables Description:

- A_f32 input matrix in the linear combination equation
- B_f32 output matrix in the linear combination equation
- X_f32 unknown matrix estimated using A_f32 & B_f32 matrices

NMSIS DSP Software Library Functions Used:

- `riscv_mat_init_f32()`
- `riscv_mat_trans_f32()`
- `riscv_mat_mult_f32()`
- `riscv_mat_inverse_f32()`

Signal Convergence Example

group **SignalConvergence**

Refer `riscv_signal_converge_example_f32.c`

Description:

Demonstrates the ability of an adaptive filter to “learn” the transfer function of a FIR lowpass filter using the Normalized LMS Filter, Finite Impulse Response (FIR) Filter, and Basic Math Functions.

Algorithm:

The figure below illustrates the signal flow in this example. Uniformly distributed white noise is passed through an FIR lowpass filter. The output of the FIR filter serves as the reference input of the adaptive filter (normalized LMS filter). The white noise is input to the adaptive filter. The adaptive filter learns the transfer function of the FIR filter. The filter outputs two signals: (1) the output of the internal adaptive FIR filter, and (2) the error signal which is the difference between the adaptive filter and the reference output of the FIR filter. Over time as the adaptive filter learns the transfer function of the FIR filter, the first output approaches the reference output of the FIR filter, and the error signal approaches zero.

The adaptive filter converges properly even if the input signal has a large dynamic range (i.e., varies from small to large values). The coefficients of the adaptive filter are initially zero, and then converge over 1536 samples. The internal function `test_signal_converge()` implements the stopping condition. The function checks if all of the values of the error signal have a magnitude below a threshold DELTA.

Block Diagram:

**Variables Description:**

- testInput_f32 points to the input data
- firStateF32 points to FIR state buffer
- lmsStateF32 points to Normalised Least mean square FIR filter state buffer
- FIRCoeff_f32 points to coefficient buffer
- lmsNormCoeff_f32 points to Normalised Least mean square FIR filter coefficient buffer
- wire1, wire2, wire3 temporary buffers
- errOutput, err_signal temporary error buffers

SineCosine Example

group **SinCosExample**

Refer riscv_sin_cos_example_f32.c

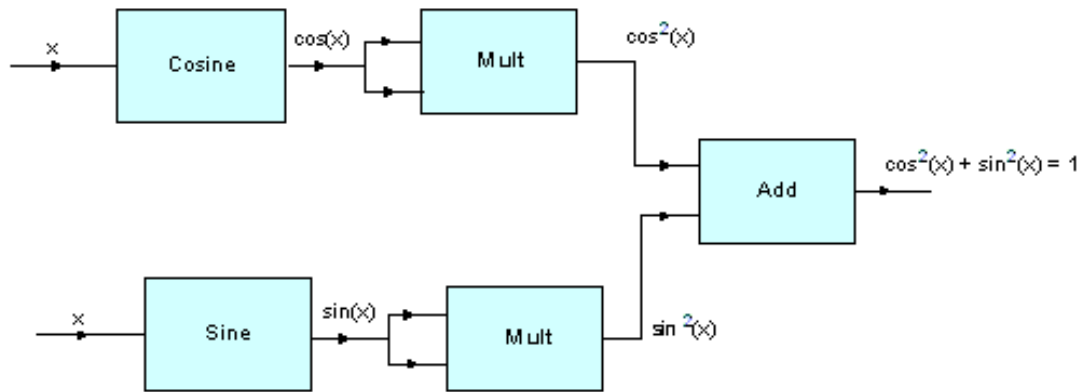

Description:

Demonstrates the Pythagorean trigonometric identity with the use of Cosine, Sine, Vector Multiplication, and Vector Addition functions.

Algorithm:

Mathematically, the Pythagorean trigonometric identity is defined by the following equation: where x is the angle in radians.

Block Diagram:

**Variables Description:**

- testInput_f32 array of input angle in radians
- testOutput stores sum of the squares of sine and cosine values of input angle

NMSIS DSP Software Library Functions Used:

- riscv_cos_f32()
- riscv_sin_f32()
- riscv_mult_f32()
- riscv_add_f32()

Variance Example

group **VarianceExample**

Refer riscv_variance_example_f32.c

Description:

Demonstrates the use of Basic Math and Support Functions to calculate the variance of an input sequence with N samples. Uniformly distributed white noise is taken as input.

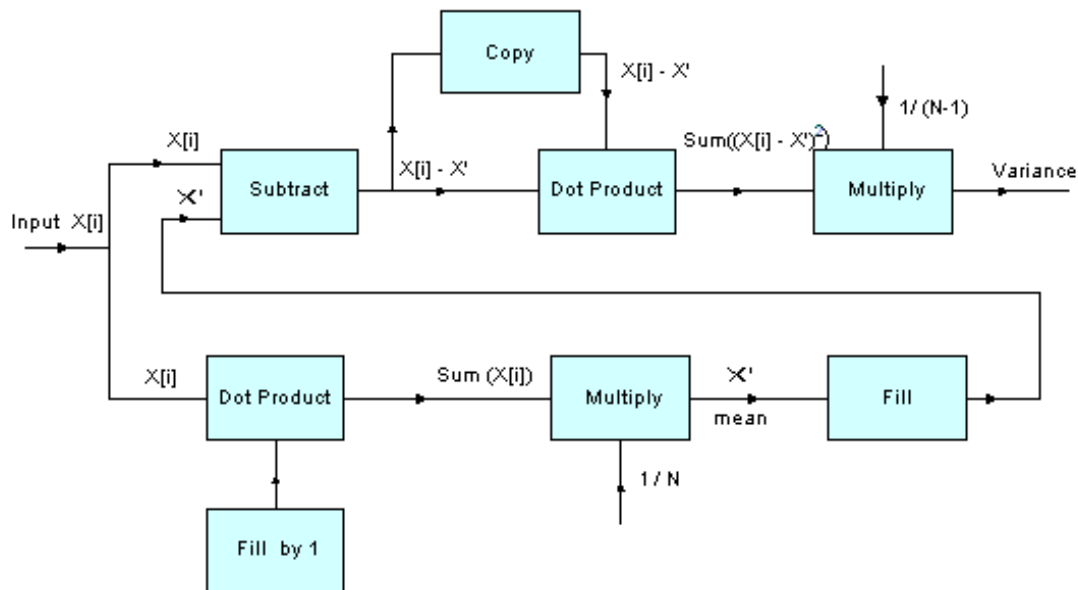

Algorithm:

The variance of a sequence is the mean of the squared deviation of the sequence from its mean.

This is denoted by the following equation: where, $x[n]$ is the input sequence, N is the number of input samples, and \bar{x} is the mean value of the input sequence, $x[n]$.

The mean value \bar{x} is defined as:

Block Diagram:

Variables Description:

- testInput_f32 points to the input data
- wire1, wir2, wire3 temporary buffers
- blockSize number of samples processed at a time
- refVarianceOut reference variance value

NMSIS DSP Software Library Functions Used:

- riscv_dot_prod_f32()
- riscv_mult_f32()
- riscv_sub_f32()
- riscv_fill_f32()
- riscv_copy_f32()

group **groupExamples**

3.4 Changelog

3.4.1 V1.0.2

This is release 1.0.2 version of NMSIS-DSP library.

- Sync up to CMSIS DSP library 1.9.0
- Adding initial support for RISC-V vector extension support
- **Caution:** `riscv_math.h` is separated into several header files. Extra `PrivateInclude` folder is included as header folder.

3.4.2 V1.0.1

This is release V1.0.1 version of NMSIS-DSP library.

- Both Nuclei RISC-V 32 and 64 bit cores are supported now.
- Libraries are optimized for RISC-V 32 and 64 bit DSP instructions.
- The NN examples are now using Nuclei SDK as running environment.

3.4.3 V1.0.0

This is the first version of NMSIS-DSP library.

We adapt the CMSIS-DSP v1.6.0 library to use RISC-V DSP instructions, all the API names now are renamed from `arm_XXX` to `riscv_XXX`.

4.1 Overview

4.1.1 Introduction

This user manual describes the NMSIS NN software library, a collection of efficient neural network kernels developed to maximize the performance and minimize the memory footprint of neural networks on Nuclei N/NX Class Processors cores.

The library is divided into a number of functions each covering a specific category:

- Neural Network Convolution Functions
- Neural Network Activation Functions
- Fully-connected Layer Functions
- Neural Network Pooling Functions
- Softmax Functions
- Neural Network Support Functions

The library has separate functions for operating on different weight and activation data types including 8-bit integers (q7_t) and 16-bit integers (q15_t). The description of the kernels are included in the function description.

The implementation details are also described in this paper [CMSIS-NN: Efficient Neural Network Kernels for Arm Cortex-M CPUs²³](#).

4.1.2 Block Diagram

4.1.3 Examples

The library ships with a number of examples which demonstrate how to use the library functions.

- *Convolutional Neural Network Example* (page 578)
- *Gated Recurrent Unit Example* (page 579)

²³ <https://arxiv.org/abs/1801.06601>

Fig. 1: NMSIS NN Block Diagram

4.1.4 Pre-processor Macros

Each library project have different pre-processor macros.

This library is only built for little endian targets.

RISCV_MATH_DSP: Define macro `RISCV_MATH_DSP`, If the silicon supports DSP instructions.

RISCV_NN_TRUNCATE: Define macro `RISCV_NN_TRUNCATE` to use floor instead of round-to-the-nearest-int for the computation.

4.2 Using NMSIS-NN

Here we will describe how to run the nmsis nn examples in Nuclei Spike.

4.2.1 Preparation

- Nuclei Modified Spike - `xl_spike`
- Nuclei SDK modified for `xl_spike` branch `dev_xlspike`
- Nuclei RISC-V GNU Toolchain
- CMake ≥ 3.5

4.2.2 Tool Setup

1. Export **PATH** correctly for `xl_spike` and `riscv-nuclei-elf-gcc`

```
export PATH=/path/to/xl_spike/bin:/path/to/riscv-nuclei-elf-gcc/bin/:$PATH
```

4.2.3 Build NMSIS NN Library

1. Download or clone NMSIS source code into **NMSIS** directory.
2. cd to `NMSIS/NMSIS/` directory

3. Build NMSIS NN library using `make gen_nn_lib`
4. Strip debug informations using `make strip_nn_lib` to make the generated library smaller
5. The nn library will be generated into `./Library/NN/GCC` folder
6. The nn libraries will be look like this:

```
$ ll Library/NN/GCC/
total 3000
-rw-r--r-- 1 hqfang nucleisys 128482 Jul 14 14:51 libnmsis_nn_rv32imac.a
-rw-r--r-- 1 hqfang nucleisys 281834 Jul 14 14:51 libnmsis_nn_rv32imacp.a
-rw-r--r-- 1 hqfang nucleisys 128402 Jul 14 14:51 libnmsis_nn_rv32imaafc.a
-rw-r--r-- 1 hqfang nucleisys 282750 Jul 14 14:51 libnmsis_nn_rv32imaafcp.a
-rw-r--r-- 1 hqfang nucleisys 128650 Jul 14 14:51 libnmsis_nn_rv32imafdc.a
-rw-r--r-- 1 hqfang nucleisys 282978 Jul 14 14:51 libnmsis_nn_rv32imafdcp.a
-rw-r--r-- 1 hqfang nucleisys 183918 Jul 14 14:51 libnmsis_nn_rv64imac.a
-rw-r--r-- 1 hqfang nucleisys 418598 Jul 14 14:51 libnmsis_nn_rv64imacp.a
-rw-r--r-- 1 hqfang nucleisys 184206 Jul 14 14:51 libnmsis_nn_rv64imaafc.a
-rw-r--r-- 1 hqfang nucleisys 418070 Jul 14 14:51 libnmsis_nn_rv64imaafcp.a
-rw-r--r-- 1 hqfang nucleisys 184454 Jul 14 14:51 libnmsis_nn_rv64imafdc.a
-rw-r--r-- 1 hqfang nucleisys 419774 Jul 14 14:51 libnmsis_nn_rv64imafdcp.a
```

7. library name with extra `p` is build with RISC-V DSP enabled.
 - `libnmsis_nn_rv32imac.a`: Build for **RISCV_ARCH=rv32imac** without DSP enabled.
 - `libnmsis_nn_rv32imacp.a`: Build for **RISCV_ARCH=rv32imac** with DSP enabled.

Note:

- You can also directly build both DSP and NN library using `make gen`
 - You can strip the generated DSP and NN library using `make strip`
-

4.2.4 How to run

1. Set environment variables `NUCLEI_SDK_ROOT` and `NUCLEI_SDK_NMSIS`, and set Nuclei SDK SoC to *xl-spike*

```
export NUCLEI_SDK_ROOT=/path/to/nuclei_sdk
export NUCLEI_SDK_NMSIS=/path/to/NMSIS/NMSIS
export SOC=xlspike
```

2. Let us take `./cifar10/` for example
2. `cd ./cifar10/`
3. Run with RISC-V DSP enabled NMSIS-NN library for CORE n307

```
# Clean project
make DSP_ENABLE=ON CORE=n307 clean
# Build project
make DSP_ENABLE=ON CORE=n307 all
# Run application using xl_spike
make DSP_ENABLE=ON CORE=n307 run
```

4. Run with RISC-V DSP disabled NMSIS-NN library for CORE n307

```
make DSP_ENABLE=OFF CORE=n307 clean
make DSP_ENABLE=OFF CORE=n307 all
make DSP_ENABLE=OFF CORE=n307 run
```

Note:

- You can easily run this example in your hardware, if you have enough memory to run it, just modify the SOC to the one you are using in step 1.
-

4.3 NMSIS NN API

If you want to access doxygen generated NMSIS NN API, please click [NMSIS NN API Doxygen Documentation](#).

4.3.1 Neural Network Functions

Neural Network Activation Functions

```
void riscv_nn_activations_direct_q15 (q15_t *data, uint16_t size, uint16_t int_width,
                                       riscv_nn_activation_type type)
```

```
void riscv_nn_activations_direct_q7 (q7_t *data, uint16_t size, uint16_t int_width,
                                      riscv_nn_activation_type type)
```

```
void riscv_relu6_s8 (q7_t *data, uint16_t size)
```

```
void riscv_relu_q15 (q15_t *data, uint16_t size)
```

```
void riscv_relu_q7 (q7_t *data, uint16_t size)
```

group **Acti**

Perform activation layers, including ReLU (Rectified Linear Unit), sigmoid and tanh

Functions

```
void riscv_nn_activations_direct_q15 (q15_t *data, uint16_t size, uint16_t int_width,
                                       riscv_nn_activation_type type)
```

neural network activation function using direct table look-up

Q15 neural network activation function using direct table look-up.

Note Refer header file for details.

```
void riscv_nn_activations_direct_q7 (q7_t *data, uint16_t size, uint16_t int_width,
                                      riscv_nn_activation_type type)
```

Q7 neural network activation function using direct table look-up.

This is the direct table look-up approach.

Parameters

- [inout] data: pointer to input
- [in] size: number of elements
- [in] int_width: bit-width of the integer part, assume to be smaller than 3

- [in] type: type of activation functions

Assume here the integer part of the fixed-point is ≤ 3 . More than 3 just not making much sense, makes no difference with saturation followed by any of these activation functions.

void **riscv_relu6_s8** (q7_t *data, uint16_t size)
s8 ReLU6 function

Parameters

- [inout] data: pointer to input
- [in] size: number of elements

void **riscv_relu_q15** (q15_t *data, uint16_t size)
Q15 RELU function.

Optimized relu with QSUB instructions.

Parameters

- [inout] data: pointer to input
- [in] size: number of elements

void **riscv_relu_q7** (q7_t *data, uint16_t size)
Q7 RELU function.

Optimized relu with QSUB instructions.

Parameters

- [inout] data: pointer to input
- [in] size: number of elements

group **NNConv**

Collection of convolution, depthwise convolution functions and their variants.

The convolution is implemented in 2 steps: im2col and GEMM

im2col is a process of converting each patch of image data into a column. After im2col, the convolution is computed as matrix-matrix multiplication.

To reduce the memory footprint, the im2col is performed partially. Each iteration, only a few column (i.e., patches) are generated and computed with GEMM kernels similar to NMSIS-DSP riscv_mat_mult functions.

Functions

```
riscv_status riscv_convolve_1_x_n_s8(const nmsis_nn_context *ctx, const nmsis_nn_conv_params *conv_params, const nmsis_nn_per_channel_quant_params *quant_params, const nmsis_nn_dims *input_dims, const q7_t *input_data, const nmsis_nn_dims *filter_dims, const q7_t *filter_data, const nmsis_nn_dims *bias_dims, const int32_t *bias_data, const nmsis_nn_dims *output_dims, q7_t *output_data)
```

1xn convolution

- Supported framework : TensorFlow Lite Micro
- The following constraints on the arguments apply
 1. input_dims->n equals 1
 2. output_dims->w is a multiple of 4
 3. Explicit constraints(since it is for 1xN convolution) -## input_dims->h equals 1 -## output_dims->h equals 1 -## filter_dims->h equals 1

Return The function returns either RISCVC_MATH_SIZE_MISMATCH if argument constraints fail. or, RISCVC_MATH_SUCCESS on successful completion.

Parameters

- [inout] ctx: Function context that contains the additional buffer if required by the function. riscv_convolve_1_x_n_s8_get_buffer_size will return the buffer_size if required
- [in] conv_params: Convolution parameters (e.g. strides, dilations, pads,...). Range of conv_params->input_offset : [-127, 128] Range of conv_params->output_offset : [-128, 127]
- [in] quant_params: Per-channel quantization info. It contains the multiplier and shift values to be applied to each output channel
- [in] input_dims: Input (activation) tensor dimensions. Format: [N, H, W, C_IN]
- [in] input_data: Input (activation) data pointer. Data type: int8
- [in] filter_dims: Filter tensor dimensions. Format: [C_OUT, 1, WK, C_IN] where WK is the horizontal spatial filter dimension
- [in] filter_data: Filter data pointer. Data type: int8
- [in] bias_dims: Bias tensor dimensions. Format: [C_OUT]
- [in] bias_data: Optional bias data pointer. Data type: int32
- [in] output_dims: Output tensor dimensions. Format: [N, H, W, C_OUT]
- [out] output_data: Output data pointer. Data type: int8

```
int32_t riscv_convolve_1_x_n_s8_get_buffer_size(const nmsis_nn_dims *input_dims, const nmsis_nn_dims *filter_dims)
```

Get the required additional buffer size for 1xn convolution.

Return The function returns required buffer size(bytes)

Parameters

- [in] input_dims: Input (activation) tensor dimensions. Format: [N, H, W, C_IN]

- [in] `filter_dims`: Filter tensor dimensions. Format: [C_OUT, 1, WK, C_IN] where WK is the horizontal spatial filter dimension

```

                                                         q7_t *Im_out, const uint16_t
                                                         dim_im_out_x, const uint16_t
                                                         dim_im_out_y, q15_t *bufferA,
                                                         q7_t *bufferB)
```

Fast Q7 version of 1x1 convolution (non-square shape)

This function is optimized for convolution with 1x1 kernel size (i.e., `dim_kernel_x=1` and `dim_kernel_y=1`). It can be used for the second half of MobileNets [1] after depthwise separable convolution.

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `Im_in`: pointer to input tensor
- [in] `dim_im_in_x`: input tensor dimension x
- [in] `dim_im_in_y`: input tensor dimension y
- [in] `ch_im_in`: number of input tensor channels
- [in] `wt`: pointer to kernel weights
- [in] `ch_im_out`: number of filters, i.e., output tensor channels
- [in] `dim_kernel_x`: filter kernel size x
- [in] `dim_kernel_y`: filter kernel size y
- [in] `padding_x`: padding size x
- [in] `padding_y`: padding size y
- [in] `stride_x`: convolution stride x
- [in] `stride_y`: convolution stride y
- [in] `bias`: pointer to bias
- [in] `bias_shift`: amount of left-shift for bias
- [in] `out_shift`: amount of right-shift for output
- [inout] `Im_out`: pointer to output tensor

- [in] dim_im_out_x: output tensor dimension x
- [in] dim_im_out_y: output tensor dimension y
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

This function is the version with full list of optimization tricks, but with some constraints: ch_im_in is multiple of 4 ch_im_out is multiple of 2

```

Fast s8 version for 1x1 convolution (non-square shape)

- Supported framework : TensorFlow Lite Micro
- The following constraints on the arguments apply
 1. input_dims->c is a multiple of 4
 2. conv_params->padding.w = conv_params->padding.h = 0
 3. conv_params->stride.w = conv_params->stride.h = 1

Return The function returns either RISCVC_MATH_SIZE_MISMATCH if argument constraints fail. or, RISCVC_MATH_SUCCESS on successful completion.

Parameters

- [inout] ctx: Function context that contains the additional buffer if required by the function. riscv_convolve_1x1_s8_fast_get_buffer_size will return the buffer_size if required
- [in] conv_params: Convolution parameters (e.g. strides, dilations, pads,...). Range of conv_params->input_offset : [-127, 128] Range of conv_params->output_offset : [-128, 127]
- [in] quant_params: Per-channel quantization info. It contains the multiplier and shift values to be applied to each output channel
- [in] input_dims: Input (activation) tensor dimensions. Format: [N, H, W, C_IN]
- [in] input_data: Input (activation) data pointer. Data type: int8
- [in] filter_dims: Filter tensor dimensions. Format: [C_OUT, 1, 1, C_IN]
- [in] filter_data: Filter data pointer. Data type: int8
- [in] bias_dims: Bias tensor dimensions. Format: [C_OUT]
- [in] bias_data: Optional bias data pointer. Data type: int32
- [in] output_dims: Output tensor dimensions. Format: [N, H, W, C_OUT]
- [out] output_data: Output data pointer. Data type: int8

```
int32_t riscv_convolve_1x1_s8_fast_get_buffer_size(const nmsis_nn_dims *input_dims)
```

Get the required buffer size for riscv_convolve_1x1_s8_fast.

Return The function returns the required buffer size in bytes

Parameters

- [in] input_dims: Input (activation) dimensions

```
riscv_status riscv_convolve_HWC_q15_basic(const q15_t *Im_in, const uint16_t dim_im_in, const uint16_t ch_im_in, const q15_t *wt, const uint16_t ch_im_out, const uint16_t dim_kernel, const uint16_t padding, const uint16_t stride, const q15_t *bias, const uint16_t bias_shift, const uint16_t out_shift, q15_t *Im_out, const uint16_t dim_im_out, q15_t *bufferA, q7_t *bufferB)
```

Basic Q15 convolution function.

Buffer size:

Return The function returns RISC_V_MATH_SUCCESS

Parameters

- [in] Im_in: pointer to input tensor
- [in] dim_im_in: input tensor dimension
- [in] ch_im_in: number of input tensor channels
- [in] wt: pointer to kernel weights
- [in] ch_im_out: number of filters, i.e., output tensor channels
- [in] dim_kernel: filter kernel size
- [in] padding: padding sizes
- [in] stride: convolution stride
- [in] bias: pointer to bias
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [inout] Im_out: pointer to output tensor
- [in] dim_im_out: output tensor dimension
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

bufferA size: ch_im_in*dim_kernel*dim_kernel

bufferB size: 0

This basic version is designed to work for any input tensor and weight dimension.

```
riscv_status riscv_convolve_HWC_q15_fast (const q15_t *Im_in, const uint16_t dim_im_in,  
                                           const uint16_t ch_im_in, const q15_t *wt,  
                                           const uint16_t ch_im_out, const uint16_t  
dim_kernel, const uint16_t padding, const  
uint16_t stride, const q15_t *bias, const

q15_t *Im_out, const uint16_t dim_im_out, q15_t  
*bufferA, q7_t *bufferB)
```

Fast Q15 convolution function.

Buffer size:

Return The function returns either RISCVMATH_SIZE_MISMATCH or RISCVMATH_SUCCESS based on the outcome of size checking.

Parameters

- [in] Im_in: pointer to input tensor
- [in] dim_im_in: input tensor dimension
- [in] ch_im_in: number of input tensor channels
- [in] wt: pointer to kernel weights
- [in] ch_im_out: number of filters, i.e., output tensor channels
- [in] dim_kernel: filter kernel size
- [in] padding: padding sizes
- [in] stride: convolution stride
- [in] bias: pointer to bias
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [inout] Im_out: pointer to output tensor
- [in] dim_im_out: output tensor dimension
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

bufferA size: 2*ch_im_in*dim_kernel*dim_kernel

bufferB size: 0

Input dimension constraints:

ch_im_in is multiple of 2

ch_im_out is multiple of 2

```

riscv_status riscv_convolve_HWC_q15_fast_nonsquare (const q15_t *Im_in, const

                                                    *bufferA, q7_t *bufferB)

```

Basic Q7 convolution function (non-square shape)

Basic Q7 convolution function (non-square shape)

Return The function returns RISC_V_MATH_SUCCESS

Parameters

- [in] Im_in: pointer to input tensor
- [in] dim_im_in_x: input tensor dimension x
- [in] dim_im_in_y: input tensor dimension y
- [in] ch_im_in: number of input tensor channels
- [in] wt: pointer to kernel weights
- [in] ch_im_out: number of filters, i.e., output tensor channels
- [in] dim_kernel_x: filter kernel size x
- [in] dim_kernel_y: filter kernel size y
- [in] padding_x: padding size x
- [in] padding_y: padding size y
- [in] stride_x: convolution stride x
- [in] stride_y: convolution stride y
- [in] bias: pointer to bias
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [inout] Im_out: pointer to output tensor
- [in] dim_im_out_x: output tensor dimension x
- [in] dim_im_out_y: output tensor dimension y
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

```
riscv_status riscv_convolve_HWC_q7_fast (const q7_t *Im_in, const uint16_t dim_im_in,  
                                         const uint16_t ch_im_in, const q7_t *wt,  
                                         const uint16_t ch_im_out, const uint16_t

                                         bias_shift, const uint16_t out_shift, q7_t *Im_out,  
                                         const uint16_t dim_im_out, q15_t *bufferA, q7_t  
                                         *bufferB)
```

Fast Q7 convolution function.

Buffer size:

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] Im_in: pointer to input tensor
- [in] dim_im_in: input tensor dimension
- [in] ch_im_in: number of input tensor channels
- [in] wt: pointer to kernel weights
- [in] ch_im_out: number of filters, i.e., output tensor channels
- [in] dim_kernel: filter kernel size
- [in] padding: padding sizes
- [in] stride: convolution stride
- [in] bias: pointer to bias
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [inout] Im_out: pointer to output tensor
- [in] dim_im_out: output tensor dimension
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

bufferA size: $2 \times \text{ch_im_in} \times \text{dim_kernel} \times \text{dim_kernel}$

bufferB size: 0

Input dimension constraints:

ch_im_in is multiple of 4 (because of the SIMD32 read and swap)

ch_im_out is multiple of 2 (because 2x2 mat_mult kernel)

The im2col converts the Q7 tensor input into Q15 column, which is stored in bufferA. There is reordering happening during this im2col process with `riscv_q7_to_q15_reordered_no_shift`. For every four elements, the second and third elements are swapped.

The computation kernel `riscv_nn_mat_mult_kernel_q7_q15_reordered` does the GEMM computation with the reordered columns.

To speed-up the determination of the padding condition, we split the computation into 3x3 parts, i.e., {top, mid, bottom} X {left, mid, right}. This reduces the total number of boundary condition checks and improves the data copying performance.

```

```

Fast Q7 convolution function (non-square shape)

This function is the version with full list of optimization tricks, but with some constraints: `ch_im_in` is multiple of 4 `ch_im_out` is multiple of 2

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `Im_in`: pointer to input tensor
- [in] `dim_im_in_x`: input tensor dimension x
- [in] `dim_im_in_y`: input tensor dimension y
- [in] `ch_im_in`: number of input tensor channels
- [in] `wt`: pointer to kernel weights
- [in] `ch_im_out`: number of filters, i.e., output tensor channels
- [in] `dim_kernel_x`: filter kernel size x
- [in] `dim_kernel_y`: filter kernel size y
- [in] `padding_x`: padding size x
- [in] `padding_y`: padding size y
- [in] `stride_x`: convolution stride x
- [in] `stride_y`: convolution stride y
- [in] `bias`: pointer to bias
- [in] `bias_shift`: amount of left-shift for bias
- [in] `out_shift`: amount of right-shift for output
- [inout] `Im_out`: pointer to output tensor
- [in] `dim_im_out_x`: output tensor dimension x
- [in] `dim_im_out_y`: output tensor dimension y
- [inout] `bufferA`: pointer to buffer space for input
- [inout] `bufferB`: pointer to buffer space for output

```
riscv_status riscv_convolve_HWC_q7_RGB(const q7_t *Im_in, const uint16_t dim_im_in,
                                       const uint16_t ch_im_in, const q7_t *wt, const
                                       uint16_t ch_im_out, const uint16_t dim_kernel,
                                       const uint16_t padding, const uint16_t stride,
                                       const q7_t *bias, const uint16_t bias_shift,
                                       const uint16_t out_shift, q7_t *Im_out, const
                                       uint16_t dim_im_out, q15_t *bufferA, q7_t *bufferB)
```

Q7 convolution function for RGB image.

Q7 version of convolution for RGB image.

Buffer size:

Return The function returns either RISCVC_MATH_SIZE_MISMATCH or RISCVC_MATH_SUCCESS based on the outcome of size checking.

Parameters

- [in] Im_in: pointer to input tensor
- [in] dim_im_in: input tensor dimension
- [in] ch_im_in: number of input tensor channels
- [in] wt: pointer to kernel weights
- [in] ch_im_out: number of filters, i.e., output tensor channels
- [in] dim_kernel: filter kernel size
- [in] padding: padding sizes
- [in] stride: convolution stride
- [in] bias: pointer to bias
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [inout] Im_out: pointer to output tensor
- [in] dim_im_out: output tensor dimension
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

bufferA size: 2*ch_im_in*dim_kernel*dim_kernel

bufferB size: 0

Input dimension constraints:

ch_im_in equals 3

This kernel is written exclusively for convolution with ch_im_in equals 3. This applies on the first layer of CNNs which has input image with RGB format.

```
riscv_status riscv_convolve_s8(const nmsis_nn_context *ctx, const nmsis_nn_conv_params
                              *conv_params, const nmsis_nn_per_channel_quant_params
                              *quant_params, const nmsis_nn_dims *input_dims, const
                              q7_t *input_data, const nmsis_nn_dims *filter_dims, const
                              q7_t *filter_data, const nmsis_nn_dims *bias_dims, const
                              int32_t *bias_data, const nmsis_nn_dims *output_dims, q7_t
                              *output_data)
```

Basic s8 convolution function.

1. Supported framework: TensorFlow Lite micro
2. q7 is used as data type eventhough it is s8 data. It is done so to be consistent with existing APIs.
3. Additional memory is required for optimization. Refer to argument 'ctx' for details.

Return The function returns `RISCV_MATH_SUCCESS`

Parameters

- [inout] `ctx`: Function context that contains the additional buffer if required by the function. `riscv_convolve_s8_get_buffer_size` will return the `buffer_size` if required
- [in] `conv_params`: Convolution parameters (e.g. strides, dilations, pads,...). Range of `conv_params->input_offset` : [-127, 128] Range of `conv_params->output_offset` : [-128, 127]
- [in] `quant_params`: Per-channel quantization info. It contains the multiplier and shift values to be applied to each output channel
- [in] `input_dims`: Input (activation) tensor dimensions. Format: [N, H, W, C_IN]
- [in] `input_data`: Input (activation) data pointer. Data type: int8
- [in] `filter_dims`: Filter tensor dimensions. Format: [C_OUT, HK, WK, C_IN] where HK and WK are the spatial filter dimensions
- [in] `filter_data`: Filter data pointer. Data type: int8
- [in] `bias_dims`: Bias tensor dimensions. Format: [C_OUT]
- [in] `bias_data`: Optional bias data pointer. Data type: int32
- [in] `output_dims`: Output tensor dimensions. Format: [N, H, W, C_OUT]
- [out] `output_data`: Output data pointer. Data type: int8

```
int32_t riscv_convolve_s8_get_buffer_size(const nmsis_nn_dims *input_dims, const
                                         nmsis_nn_dims *filter_dims)
```

Get the required buffer size for s8 convolution function.

Return The function returns required buffer size(bytes)

Parameters

- [in] `input_dims`: Input (activation) tensor dimensions. Format: [N, H, W, C_IN]
- [in] `filter_dims`: Filter tensor dimensions. Format: [C_OUT, HK, WK, C_IN] where HK and WK are the spatial filter dimensions

```
riscv_status riscv_convolve_wrapper_s8(const nmsis_nn_context *ctx, const nmsis_nn_conv_params *conv_params, const nmsis_nn_per_channel_quant_params *quant_params,
const nmsis_nn_dims *input_dims, const q7_t *input_data, const nmsis_nn_dims *filter_dims,
const q7_t *filter_data, const nmsis_nn_dims *bias_dims, const int32_t *bias_data, const
nmsis_nn_dims *output_dims, q7_t *output_data)
```

s8 convolution layer wrapper function with the main purpose to call the optimal kernel available in nmsis-nn to perform the convolution.

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` if argument constraints fail. or, `RISCV_MATH_SUCCESS` on successful completion.

Parameters

- [inout] `ctx`: Function context that contains the additional buffer if required by the function. `riscv_convolve_wrapper_s8_get_buffer_size` will return the `buffer_size` if required
- [in] `conv_params`: Convolution parameters (e.g. strides, dilations, pads,...). Range of `conv_params->input_offset` : [-127, 128] Range of `conv_params->output_offset` : [-128, 127]
- [in] `quant_params`: Per-channel quantization info. It contains the multiplier and shift values to be applied to each output channel
- [in] `input_dims`: Input (activation) tensor dimensions. Format: [N, H, W, C_IN]
- [in] `input_data`: Input (activation) data pointer. Data type: int8
- [in] `filter_dims`: Filter tensor dimensions. Format: [C_OUT, HK, WK, C_IN] where HK and WK are the spatial filter dimensions
- [in] `filter_data`: Filter data pointer. Data type: int8
- [in] `bias_dims`: Bias tensor dimensions. Format: [C_OUT]
- [in] `bias_data`: Bias data pointer. Data type: int32
- [in] `output_dims`: Output tensor dimensions. Format: [N, H, W, C_OUT]
- [out] `output_data`: Output data pointer. Data type: int8

```
int32_t riscv_convolve_wrapper_s8_get_buffer_size (const nmsis_nn_conv_params
                                                    *conv_params, const nmsis_nn_dims *input_dims, const nmsis_nn_dims *filter_dims,
                                                    const nmsis_nn_dims *output_dims)
```

Get the required buffer size for `riscv_convolve_wrapper_s8`.

Return The function returns required buffer size(bytes)

Parameters

- [in] `conv_params`: Convolution parameters (e.g. strides, dilations, pads,...). Range of `conv_params->input_offset` : [-127, 128] Range of `conv_params->output_offset` : [-128, 127]
- [in] `input_dims`: Input (activation) dimensions. Format: [N, H, W, C_IN]
- [in] `filter_dims`: Filter dimensions. Format: [C_OUT, HK, WK, C_IN] where HK and WK are the spatial filter dimensions
- [in] `output_dims`: Output tensor dimensions. Format: [N, H, W, C_OUT]

```
riscv_status riscv_depthwise_conv_3x3_s8 (const nmsis_nn_context *ctx, const nmsis_nn_dw_conv_params *dw_conv_params,
const nmsis_nn_per_channel_quant_params *quant_params, const nmsis_nn_dims *input_dims, const q7_t *input_data, const nmsis_nn_dims *filter_dims, const q7_t *filter_data,
const nmsis_nn_dims *bias_dims, const int32_t *bias_data, const nmsis_nn_dims *output_dims, q7_t *output_data)
```

Optimized s8 depthwise convolution function for 3x3 kernel size with some constraints on the input arguments(documented below). Refer `riscv_depthwise_conv_s8()` for function argument details.

- Supported framework : TensorFlow Lite Micro
- The following constrains on the arguments apply
 1. Number of input channel equals number of output channels
 2. Filter height and width equals 3
 3. Padding along x is either 0 or 1.

Return The function returns one of the following `RISCV_MATH_SIZE_MISMATCH` - Unsupported dimension of tensors `RISCV_MATH_ARGUMENT_ERROR` - Unsupported pad size along the x axis `RISCV_MATH_SUCCESS` - Successful operation

```
static void depthwise_conv_s8_mult_4(const int8_t *input, const int32_t input_x,

*output_dims, q7_t *output_data)
```

Basic s8 depthwise convolution function that doesn't have any constraints on the input dimensions.

- Supported framework: TensorFlow Lite
- q7 is used as data type eventhough it is s8 data. It is done so to be consistent with existing APIs.

Return The function returns `RISCV_MATH_SUCCESS`

Parameters

- [inout] `ctx`: Function context (e.g. temporary buffer). Check the function definition file to see if an additional buffer is required. Optional function `{API}_get_buffer_size()` provides the buffer size if an additional buffer is required. exists if additional memory is.
- [in] `dw_conv_params`: Depthwise convolution parameters (e.g. strides, dilations, pads,...) `dw_conv_params->dilation` is not used. Range of `dw_conv_params->input_offset` : [-127, 128] Range of `dw_conv_params->input_offset` : [-128, 127]
- [in] `quant_params`: Per-channel quantization info. It contains the multiplier and shift values to be applied to each output channel
- [in] `input_dims`: Input (activation) tensor dimensions. Format: [1, H, W, C_IN] Batch argument N is not used.
- [in] `input_data`: Input (activation) data pointer. Data type: int8
- [in] `filter_dims`: Filter tensor dimensions. Format: [1, H, W, C_OUT]
- [in] `filter_data`: Filter data pointer. Data type: int8
- [in] `bias_dims`: Bias tensor dimensions. Format: [C_OUT]
- [in] `bias_data`: Bias data pointer. Data type: int32
- [in] `output_dims`: Output tensor dimensions. Format: [1, H, W, C_OUT]
- [inout] `output_data`: Output data pointer. Data type: int8

```
riscv_status riscv_depthwise_conv_s8_opt (const nmsis_nn_context *ctx, const nmsis_nn_dw_conv_params *dw_conv_params,
const nmsis_nn_per_channel_quant_params *quant_params, const nmsis_nn_dims *input_dims, const q7_t *input_data, const nmsis_nn_dims *filter_dims, const q7_t *filter_data,
const nmsis_nn_dims *bias_dims, const int32_t *bias_data, const nmsis_nn_dims *output_dims, q7_t *output_data)
```

Optimized s8 depthwise convolution function with constraint that in_channel equals out_channel. Refer `riscv_depthwise_conv_s8()` for function argument details.

- Supported framework: TensorFlow Lite
- The following constraints on the arguments apply
 1. Number of input channel equals number of output channels or `ch_mult` equals 1
- q7 is used as data type even though it is s8 data. It is done so to be consistent with existing APIs.
- Recommended when number of channels is 4 or greater.

Return The function returns one of the following `RISCV_MATH_SIZE_MISMATCH` - input channel != output channel or `ch_mult != 1` `RISCV_MATH_SUCCESS` - Successful operation

Note If number of channels is not a multiple of 4, upto 3 elements outside the boundary will be read out for the following if MVE optimizations(Arm Helium Technology) are used.

- Output shift
- Output multiplier
- Output bias

- kernel

```
int32_t riscv_depthwise_conv_s8_opt_get_buffer_size(const nmsis_nn_dims
                                                    *input_dims, const nmsis_nn_dims *filter_dims)
```

Get the required buffer size for optimized s8 depthwise convolution function with constraint that in_channel equals out_channel.

Return The function returns required buffer size in bytes

Parameters

- [in] input_dims: Input (activation) tensor dimensions. Format: [1, H, W, C_IN] Batch argument N is not used.
- [in] filter_dims: Filter tensor dimensions. Format: [1, H, W, C_OUT]

```
static void depthwise_conv_u8_mult_4(const uint8_t *input, const int32_t input_x,
                                     const int32_t input_y, const int32_t input_ch,

uint8 depthwise convolution function with asymmetric quantization

uint8 depthwise convolution function with asymmetric quantization Unless specified otherwise, arguments are mandatory.

Return The function returns one of the following RISC_V_MATH_SIZE_MISMATCH - Not supported dimension of tensors RISC_V_MATH_SUCCESS - Successful operation RISC_V_MATH_ARGUMENT_ERROR - Implementation not available

Parameters

- [in] input: Pointer to input tensor
- [in] input_x: Width of input tensor
- [in] input_y: Height of input tensor
- [in] input_ch: Channels in input tensor
- [in] kernel: Pointer to kernel weights
- [in] kernel_x: Width of kernel
- [in] kernel_y: Height of kernel
- [in] ch_mult: Number of channel multiplier
- [in] pad_x: Padding sizes x
- [in] pad_y: Padding sizes y
- [in] stride_x: Convolution stride along the width
- [in] stride_y: Convolution stride along the height
- [in] dilation_x: Dilation along width. Not used and intended for future enhancement.
- [in] dilation_y: Dilation along height. Not used and intended for future enhancement.
- [in] bias: Pointer to optional bias values. If no bias is available, NULL is expected
- [in] input_offset: Input tensor zero offset
- [in] filter_offset: Kernel tensor zero offset

- [in] output_offset: Output tensor zero offset
- [inout] output: Pointer to output tensor
- [in] output_x: Width of output tensor
- [in] output_y: Height of output tensor
- [in] output_activation_min: Minimum value to clamp the output to. Range : {0, 255}
- [in] output_activation_max: Minimum value to clamp the output to. Range : {0, 255}
- [in] output_shift: Amount of right-shift for output
- [in] output_mult: Output multiplier for requantization

```
riscv_status riscv_depthwise_conv_wrapper_s8 (const nmsis_nn_context *ctx,
                                              const nmsis_nn_dw_conv_params
                                              *dw_conv_params, const nmsis_nn_per_channel_quant_params

                                              const nmsis_nn_dims *filter_dims, const
                                              q7_t *filter_data, const nmsis_nn_dims
                                              *bias_dims, const int32_t *bias_data,
                                              const nmsis_nn_dims *output_dims, q7_t
                                              *output_data)
```

Wrapper function to pick the right optimized s8 depthwise convolution function.

- Supported framework: TensorFlow Lite
- Picks one of the the following functions
 1. riscv_depthwise_conv_s8()
 2. riscv_depthwise_conv_3x3_s8() - RISC-V CPUs with DSP extension only
 3. riscv_depthwise_conv_s8_opt()
- q7 is used as data type eventhough it is s8 data. It is done so to be consistent with existing APIs.
- Check details of riscv_depthwise_conv_s8_opt() for potential data that can be accessed outside of the boundary.

Return The function returns RISC_V_MATH_SUCCESS - Successful completion.

Parameters

- [inout] ctx: Function context (e.g. temporary buffer). Check the function definition file to see if an additional buffer is required. Optional function {API}_get_buffer_size() provides the buffer size if required.
- [in] dw_conv_params: Depthwise convolution parameters (e.g. strides, dilations, pads,...) dw_conv_params->dilation is not used. Range of dw_conv_params->input_offset : [-127, 128] Range of dw_conv_params->output_offset : [-128, 127]
- [in] quant_params: Per-channel quantization info. It contains the multiplier and shift values to be applied to each output channel
- [in] input_dims: Input (activation) tensor dimensions. Format: [H, W, C_IN] Batch argument N is not used and assumed to be 1.
- [in] input_data: Input (activation) data pointer. Data type: int8

- [in] `filter_dims`: Filter tensor dimensions. Format: [1, H, W, C_OUT]
- [in] `filter_data`: Filter data pointer. Data type: int8
- [in] `bias_dims`: Bias tensor dimensions. Format: [C_OUT]
- [in] `bias_data`: Bias data pointer. Data type: int32
- [in] `output_dims`: Output tensor dimensions. Format: [1, H, W, C_OUT]
- [inout] `output_data`: Output data pointer. Data type: int8

```
int32_t riscv_depthwise_conv_wrapper_s8_get_buffer_size (const nm-
                                                         sis_nn_dw_conv_params
                                                         *dw_conv_params,

                                                         uint16_t stride, const q7_t *bias,
                                                         const uint16_t bias_shift, const
                                                         uint16_t out_shift, q7_t *Im_out,
                                                         const uint16_t dim_im_out, q15_t
                                                         *bufferA, q7_t *bufferB)
```

Q7 depthwise separable convolution function.

Buffer size:

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `Im_in`: pointer to input tensor
- [in] `dim_im_in`: input tensor dimension
- [in] `ch_im_in`: number of input tensor channels

- [in] wt: pointer to kernel weights
- [in] ch_im_out: number of filters, i.e., output tensor channels
- [in] dim_kernel: filter kernel size
- [in] padding: padding sizes
- [in] stride: convolution stride
- [in] bias: pointer to bias
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [inout] Im_out: pointer to output tensor
- [in] dim_im_out: output tensor dimension
- [inout] bufferA: pointer to buffer space for input
- [inout] bufferB: pointer to buffer space for output

bufferA size: $2 * \text{ch_im_in} * \text{dim_kernel} * \text{dim_kernel}$

bufferB size: 0

Input dimension constraints:

ch_im_in equals ch_im_out

Implementation: There are 3 nested loop here: Inner loop: calculate each output value with MAC instruction over an accumulator Mid loop: loop over different output channel Outer loop: loop over different output (x, y)

```
riscv_status riscv_depthwise_separable_conv_HWC_q7_nonsquare (const q7_t *Im_in,

                                                             q7_t *Im_out,
                                                             const uint16_t
                                                             dim_im_out_x,
                                                             const uint16_t
                                                             dim_im_out_y,
                                                             q15_t *bufferA, q7_t
                                                             *bufferB)
```

Q7 depthwise separable convolution function (non-square shape)

This function is the version with full list of optimization tricks, but with some constraints: `ch_im_in` is equal to `ch_im_out`

Return The function returns either `RISCV_MATH_SIZE_MISMATCH` or `RISCV_MATH_SUCCESS` based on the outcome of size checking.

Parameters

- [in] `Im_in`: pointer to input tensor
- [in] `dim_im_in_x`: input tensor dimension x
- [in] `dim_im_in_y`: input tensor dimension y
- [in] `ch_im_in`: number of input tensor channels
- [in] `wt`: pointer to kernel weights
- [in] `ch_im_out`: number of filters, i.e., output tensor channels
- [in] `dim_kernel_x`: filter kernel size x
- [in] `dim_kernel_y`: filter kernel size y
- [in] `padding_x`: padding sizes x
- [in] `padding_y`: padding sizes y
- [in] `stride_x`: convolution stride x

- [in] `stride_y`: convolution stride y
- [in] `bias`: pointer to bias
- [in] `bias_shift`: amount of left-shift for bias
- [in] `out_shift`: amount of right-shift for output
- [inout] `Im_out`: pointer to output tensor
- [in] `dim_im_out_x`: output tensor dimension x
- [in] `dim_im_out_y`: output tensor dimension y
- [inout] `bufferA`: pointer to buffer space for input
- [inout] `bufferB`: pointer to buffer space for output

Fully-connected Layer Functions

USE_INTRINSIC*group* **FC**

Collection of fully-connected and matrix multiplication functions.

Fully-connected layer is basically a matrix-vector multiplication with bias. The matrix is the weights and the input/output vectors are the activation values. Supported {weight, activation} precisions include {8-bit, 8-bit}, {16-bit, 16-bit}, and {8-bit, 16-bit}.

Here we have two types of kernel functions. The basic function implements the function using regular GEMV approach. The opt functions operates with weights in interleaved formats.

Defines**USE_INTRINSIC**

Mixed Q15-Q7 opt fully-connected layer function.

Buffer size:

Return The function returns RISCV_MATH_SUCCESS

Parameters

- [in] pV: pointer to input vector
- [in] pM: pointer to matrix weights
- [in] dim_vec: length of the vector
- [in] num_of_rows: number of rows in weight matrix
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [in] bias: pointer to bias
- [inout] pOut: pointer to output vector
- [inout] vec_buffer: pointer to buffer space for input

vec_buffer size: 0

Q7_Q15 version of the fully connected layer

Weights are in q7_t and Activations are in q15_t

Limitation: x4 version requires weight reordering to work

Here we use only one pointer to read 4 rows in the weight matrix. So if the original q7_t matrix looks like this:

| a11 | a12 | a13 | a14 | a15 | a16 | a17 |

| a21 | a22 | a23 | a24 | a25 | a26 | a27 |

| a31 | a32 | a33 | a34 | a35 | a36 | a37 |

| a41 | a42 | a43 | a44 | a45 | a46 | a47 |

| a51 | a52 | a53 | a54 | a55 | a56 | a57 |

| a61 | a62 | a63 | a64 | a65 | a66 | a67 |

We operates on multiple-of-4 rows, so the first four rows becomes

a11	a21	a12	a22	a31	a41	a32	a42
a13	a23	a14	a24	a33	a43	a34	a44
a15	a25	a16	a26	a35	a45	a36	a46

The column left over will be in-order. which is: | a17 | a27 | a37 | a47 |

For the left-over rows, we do 1x1 computation, so the data remains as its original order.

So the stored weight matrix looks like this:

a11	a21	a12	a22	a31	a41
a32	a42	a13	a23	a14	a24
a33	a43	a34	a44	a15	a25
a16	a26	a35	a45	a36	a46
a17	a27	a37	a47	a51	a52
a53	a54	a55	a56	a57	a61
a62	a63	a64	a65	a66	a67

Functions

```
riscv_status riscv_fully_connected_mat_q7_vec_q15 (const q15_t *pV, const q7_t *pM,
                                                    const uint16_t dim_vec, const
                                                    uint16_t num_of_rows, const
                                                    uint16_t bias_shift, const uint16_t
                                                    out_shift, const q7_t *bias, q15_t
                                                    *pOut, q15_t *vec_buffer)
```

Mixed Q15-Q7 fully-connected layer function.

Buffer size:

Return The function returns RISCVMATH_SUCCESS

Parameters

- [in] pV: pointer to input vector
- [in] pM: pointer to matrix weights
- [in] dim_vec: length of the vector
- [in] num_of_rows: number of rows in weight matrix
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [in] bias: pointer to bias
- [inout] pOut: pointer to output vector
- [inout] vec_buffer: pointer to buffer space for input

vec_buffer size: 0

Q7_Q15 version of the fully connected layer

Weights are in q7_t and Activations are in q15_t

```
riscv_status riscv_fully_connected_mat_q7_vec_q15_opt (const q15_t *pV, const q7_t  
                                                    *pM, const uint16_t dim_vec,  
                                                    const uint16_t num_of_rows,  
                                                    const uint16_t bias_shift,  
                                                    const uint16_t out_shift,  
                                                    const q7_t *bias, q15_t  
                                                    *pOut, q15_t *vec_buffer)
```

Mixed Q15-Q7 opt fully-connected layer function.

Return The function returns RISCVMATH_SUCCESS

Parameters

- [in] pV: pointer to input vector
- [in] pM: pointer to matrix weights
- [in] dim_vec: length of the vector
- [in] num_of_rows: number of rows in weight matrix
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [in] bias: pointer to bias
- [inout] pOut: pointer to output vector
- [inout] vec_buffer: pointer to buffer space for input

```
riscv_status riscv_fully_connected_q15 (const q15_t *pV, const q15_t *pM, const  
                                         uint16_t dim_vec, const uint16_t num_of_rows,  
                                         const uint16_t bias_shift, const uint16_t out_shift,  
                                         const q15_t *bias, q15_t *pOut, q15_t *vec_buffer)
```

Q15 opt fully-connected layer function.

Q15 basic fully-connected layer function.

Buffer size:

Return The function returns RISCVMATH_SUCCESS

Parameters

- [in] pV: pointer to input vector
- [in] pM: pointer to matrix weights
- [in] dim_vec: length of the vector
- [in] num_of_rows: number of rows in weight matrix
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [in] bias: pointer to bias
- [inout] pOut: pointer to output vector
- [inout] vec_buffer: pointer to buffer space for input

vec_buffer size: 0

```
riscv_status riscv_fully_connected_q15_opt (const q15_t *pV, const q15_t *pM,
                                             const uint16_t dim_vec, const uint16_t
                                             num_of_rows, const uint16_t bias_shift,
                                             const uint16_t out_shift, const q15_t *bias,
                                             q15_t *pOut, q15_t *vec_buffer)
```

Q15 opt fully-connected layer function.

Buffer size:

Return The function returns RISC_V_MATH_SUCCESS

Parameters

- [in] pV: pointer to input vector
- [in] pM: pointer to matrix weights
- [in] dim_vec: length of the vector
- [in] num_of_rows: number of rows in weight matrix
- [in] bias_shift: amount of left-shift for bias
- [in] out_shift: amount of right-shift for output
- [in] bias: pointer to bias
- [inout] pOut: pointer to output vector
- [inout] vec_buffer: pointer to buffer space for input

vec_buffer size: 0

Here we use only one pointer to read 4 rows in the weight matrix. So if the original matrix looks like this:

```
| a11 | a12 | a13 |
| a21 | a22 | a23 |
| a31 | a32 | a33 |
| a41 | a42 | a43 |
| a51 | a52 | a53 |
| a61 | a62 | a63 |
```

We operate on multiple-of-4 rows, so the first four rows become

```
| a11 | a12 | a21 | a22 | a31 | a32 | a41 | a42 |
| a13 | a23 | a33 | a43 |
```

Remaining rows are kept the same original order.

So the stored weight matrix looks like this:

```
| a11 | a12 | a21 | a22 | a31 | a32 | a41 | a42 |
| a13 | a23 | a33 | a43 | a51 | a52 | a53 | a61 |
| a62 | a63 |
```

```
riscv_status riscv_fully_connected_q7 (const q7_t *pV, const q7_t *pM, const uint16_t
                                          dim_vec, const uint16_t num_of_rows, const
                                          uint16_t bias_shift, const uint16_t out_shift, const
                                          q7_t *bias, q7_t *pOut, q15_t *vec_buffer)
```

Q7 basic fully-connected layer function.

Buffer size:**Return** The function returns `RISCV_MATH_SUCCESS`**Parameters**

- [in] `pV`: pointer to input vector
- [in] `pM`: pointer to matrix weights
- [in] `dim_vec`: length of the vector
- [in] `num_of_rows`: number of rows in weight matrix
- [in] `bias_shift`: amount of left-shift for bias
- [in] `out_shift`: amount of right-shift for output
- [in] `bias`: pointer to bias
- [inout] `pOut`: pointer to output vector
- [inout] `vec_buffer`: pointer to buffer space for input

`vec_buffer` size: `dim_vec`

This basic function is designed to work with regular weight matrix without interleaving.

```
riscv_status riscv_fully_connected_q7_opt (const q7_t *pV, const q7_t *pM, const
                                         uint16_t dim_vec, const uint16_t num_of_rows,
                                         const uint16_t bias_shift, const uint16_t
                                         out_shift, const q7_t *bias, q7_t *pOut, q15_t
                                         *vec_buffer)
```

Q7 opt fully-connected layer function.

Buffer size:**Return** The function returns `RISCV_MATH_SUCCESS`**Parameters**

- [in] `pV`: pointer to input vector
- [in] `pM`: pointer to matrix weights
- [in] `dim_vec`: length of the vector
- [in] `num_of_rows`: number of rows in weight matrix
- [in] `bias_shift`: amount of left-shift for bias
- [in] `out_shift`: amount of right-shift for output
- [in] `bias`: pointer to bias
- [inout] `pOut`: pointer to output vector
- [inout] `vec_buffer`: pointer to buffer space for input

`vec_buffer` size: `dim_vec`

This opt function is designed to work with interleaved weight matrix. The vector input is assumed in `q7_t` format, we call `riscv_q7_to_q15_no_shift_shuffle` function to expand into `q15_t` format with certain weight re-ordering, refer to the function comments for more details. Here we use only one pointer to read 4 rows in the weight matrix. So if the original `q7_t` matrix looks like this:

```
| a11 | a12 | a13 | a14 | a15 | a16 | a17 |
| a21 | a22 | a23 | a24 | a25 | a26 | a27 |
```

```
| a31 | a32 | a33 | a34 | a35 | a36 | a37 |
| a41 | a42 | a43 | a44 | a45 | a46 | a47 |
| a51 | a52 | a53 | a54 | a55 | a56 | a57 |
| a61 | a62 | a63 | a64 | a65 | a66 | a67 |
```

We operates on multiple-of-4 rows, so the first four rows becomes

```
| a11 | a21 | a13 | a23 | a31 | a41 | a33 | a43 |
| a12 | a22 | a14 | a24 | a32 | a42 | a34 | a44 |
| a15 | a25 | a35 | a45 | a16 | a26 | a36 | a46 |
```

So within the kernel, we first read the re-ordered vector in as:

```
| b1 | b3 | and | b2 | b4 |
```

the four q31_t weights will look like

```
| a11 | a13 |, | a21 | a23 |, | a31 | a33 |, | a41 | a43 |
| a12 | a14 |, | a22 | a24 |, | a32 | a34 |, | a42 | a44 |
```

The column left over will be in-order. which is:

```
| a17 | a27 | a37 | a47 |
```

For the left-over rows, we do 1x1 computation, so the data remains as its original order.

So the stored weight matrix looks like this:

```
| a11 | a21 | a13 | a23 | a31 | a41 |
| a33 | a43 | a12 | a22 | a14 | a24 |
| a32 | a42 | a34 | a44 | a15 | a25 |
| a35 | a45 | a16 | a26 | a36 | a46 |
| a17 | a27 | a37 | a47 | a51 | a52 |
| a53 | a54 | a55 | a56 | a57 | a61 |

riscv_status riscv_fully_connected_s8(const nmsis_nn_context *ctx, const nmsis_nn_fc_params *fc_params, const nmsis_nn_per_tensor_quant_params *quant_params, const nmsis_nn_dims *input_dims, const q7_t *input_data, const nmsis_nn_dims *filter_dims, const q7_t *filter_data, const nmsis_nn_dims *bias_dims, const int32_t *bias_data, const nmsis_nn_dims *output_dims, q7_t *output_data)
```

Basic s8 Fully Connected function.

- Supported framework: TensorFlow Lite
- q7 is used as data type eventhough it is s8 data. It is done so to be consistent with existing APIs.

Return The function returns RISCV_MATH_SUCCESS

Parameters

- [inout] `ctx`: Function context (e.g. temporary buffer). Check the function definition file to see if an additional buffer is required. Optional function `{API}_get_buffer_size()` provides the buffer size if an additional buffer is required.
- [in] `fc_params`: Fully Connected layer parameters (e.g. strides, dilations, pads,...) Range of `fc_params->input_offset` : [-127, 128] `fc_params->filter_offset` : 0 Range of `fc_params->output_offset` : [-128, 127]
- [in] `quant_params`: Per-tensor quantization info. It contains the multiplier and shift values to be applied to the output tensor.
- [in] `input_dims`: Input (activation) tensor dimensions. Format: [N, H, W, C_IN] Input dimension is taken as $N \times (H * W * C_{IN})$
- [in] `input_data`: Input (activation) data pointer. Data type: int8
- [in] `filter_dims`: Two dimensional filter dimensions. Format: [N, C] N : accumulation depth and equals $(H * W * C_{IN})$ from `input_dims` C : output depth and equals `C_OUT` in `output_dims` H & W : Not used
- [in] `filter_data`: Filter data pointer. Data type: int8
- [in] `bias_dims`: Bias tensor dimensions. Format: [C_OUT] N, H, W : Not used
- [in] `bias_data`: Bias data pointer. Data type: int32
- [in] `output_dims`: Output tensor dimensions. Format: [N, C_OUT] N : Batches `C_OUT` : Output depth H & W : Not used.
- [inout] `output_data`: Output data pointer. Data type: int8

```
int32_t riscv_fully_connected_s8_get_buffer_size(const nmsis_nn_dims *filter_dims)
```

Get the required buffer size for S8 basic fully-connected and matrix multiplication layer function for TF Lite.

Return The function returns required buffer size in bytes

Parameters

- [in] `filter_dims`: dimension of filter

Neural Network Pooling Functions

```
riscv_status riscv_avgpool_s8(const nmsis_nn_context *ctx, const nmsis_nn_pool_params  
    *pool_params, const nmsis_nn_dims *input_dims, const q7_t *input_data,  
    const nmsis_nn_dims *filter_dims, const nmsis_nn_dims *output_dims,  
    q7_t *output_data)
```

```
int32_t riscv_avgpool_s8_get_buffer_size(const int dim_dst_width, const int ch_src)
```

```
riscv_status riscv_maxpool_s8(const nmsis_nn_context *ctx, const nmsis_nn_pool_params  
    *pool_params, const nmsis_nn_dims *input_dims, const q7_t *input_data,  
    const nmsis_nn_dims *filter_dims, const nmsis_nn_dims *output_dims,  
    q7_t *output_data)
```

```
void riscv_maxpool_q7_HWC(q7_t *Im_in, const uint16_t dim_im_in, const uint16_t ch_im_in,  
    const uint16_t dim_kernel, const uint16_t padding, const uint16_t stride,  
    const uint16_t dim_im_out, q7_t *bufferA, q7_t *Im_out)
```

```
void riscv_avepool_q7_HWC(q7_t *Im_in, const uint16_t dim_im_in, const uint16_t ch_im_in,
const uint16_t dim_kernel, const uint16_t padding, const uint16_t
stride, const uint16_t dim_im_out, q7_t *bufferA, q7_t *Im_out)
```

group **Pooling**

Perform pooling functions, including max pooling and average pooling

Functions

```
riscv_status riscv_avgpool_s8(const nmsis_nn_context *ctx, const nmsis_nn_pool_params
*pool_params, const nmsis_nn_dims *input_dims, const q7_t
*input_data, const nmsis_nn_dims *filter_dims, const nm-
sis_nn_dims *output_dims, q7_t *output_data)
```

s8 average pooling function.

- Supported Framework: TensorFlow Lite

Return The function returns RISC_V_MATH_SUCCESS - Successful operation

Parameters

- [inout] ctx: Function context (e.g. temporary buffer). Check the function definition file to see if an additional buffer is required. Optional function {API}_get_buffer_size() provides the buffer size if an additional buffer is required.
- [in] pool_params: Pooling parameters
- [in] input_dims: Input (activation) tensor dimensions. Format: [H, W, C_IN] Argument 'N' is not used.
- [in] input_data: Input (activation) data pointer. Data type: int8
- [in] filter_dims: Filter tensor dimensions. Format: [H, W] Argument N and C are not used.
- [in] output_dims: Output tensor dimensions. Format: [H, W, C_OUT] Argument N is not used. C_OUT equals C_IN.
- [inout] output_data: Output data pointer. Data type: int8

```
int32_t riscv_avgpool_s8_get_buffer_size(const int dim_dst_width, const int ch_src)
```

Get the required buffer size for S8 average pooling function.

Return The function returns required buffer size in bytes

Parameters

- [in] dim_dst_width: output tensor dimension
- [in] ch_src: number of input tensor channels

```
riscv_status riscv_max_pool_s8(const nmsis_nn_context *ctx, const nmsis_nn_pool_params
*pool_params, const nmsis_nn_dims *input_dims, const q7_t
*input_data, const nmsis_nn_dims *filter_dims, const nm-
sis_nn_dims *output_dims, q7_t *output_data)
```

s8 max pooling function.

- Supported Framework: TensorFlow Lite

Return The function returns RISC_V_MATH_SUCCESS - Successful operation

Parameters

- [inout] *ctx*: Function context (e.g. temporary buffer). Check the function definition file to see if an additional buffer is required. Optional function `{API}_get_buffer_size()` provides the buffer size if an additional buffer is required.
- [in] *pool_params*: Pooling parameters
- [in] *input_dims*: Input (activation) tensor dimensions. Format: [H, W, C_IN] Argument 'N' is not used.
- [in] *input_data*: Input (activation) data pointer. Data type: int8
- [in] *filter_dims*: Filter tensor dimensions. Format: [H, W] Argument N and C are not used.
- [in] *output_dims*: Output tensor dimensions. Format: [H, W, C_OUT] Argument N is not used. C_OUT equals C_IN.
- [inout] *output_data*: Output data pointer. Data type: int8

```
void riscv_maxpool_q7_HWC (q7_t *Im_in, const uint16_t dim_im_in, const uint16_t ch_im_in,  
                          const uint16_t dim_kernel, const uint16_t padding, const  
                          uint16_t stride, const uint16_t dim_im_out, q7_t *bufferA, q7_t  
                          *Im_out)
```

Q7 max pooling function.

The pooling function is implemented as split x-pooling then y-pooling.

Parameters

- [inout] *Im_in*: pointer to input tensor
- [in] *dim_im_in*: input tensor dimension
- [in] *ch_im_in*: number of input tensor channels
- [in] *dim_kernel*: filter kernel size
- [in] *padding*: padding sizes
- [in] *stride*: convolution stride
- [in] *dim_im_out*: output tensor dimension
- [inout] *bufferA*: Not used
- [inout] *Im_out*: pointer to output tensor

This pooling function is input-destructive. Input data is undefined after calling this function.

```
void riscv_avepool_q7_HWC (q7_t *Im_in, const uint16_t dim_im_in, const uint16_t ch_im_in,  
                          const uint16_t dim_kernel, const uint16_t padding, const  
                          uint16_t stride, const uint16_t dim_im_out, q7_t *bufferA, q7_t  
                          *Im_out)
```

Q7 average pooling function.

Buffer size:**Parameters**

- [inout] *Im_in*: pointer to input tensor
- [in] *dim_im_in*: input tensor dimension
- [in] *ch_im_in*: number of input tensor channels

- [in] `dim_kernel`: filter kernel size
- [in] `padding`: padding sizes
- [in] `stride`: convolution stride
- [in] `dim_im_out`: output tensor dimension
- [inout] `bufferA`: pointer to buffer space for input
- [inout] `Im_out`: pointer to output tensor

`bufferA` size: $2 * \text{dim_im_out} * \text{ch_im_in}$

The pooling function is implemented as split x-pooling then y-pooling.

This pooling function is input-destructive. Input data is undefined after calling this function.

Softmax Functions

```
void riscv_softmax_q15 (const q15_t *vec_in, const uint16_t dim_vec, q15_t *p_out)
```

```
void riscv_softmax_q7 (const q7_t *vec_in, const uint16_t dim_vec, q7_t *p_out)
```

```
void riscv_softmax_s8 (const int8_t *input, const int32_t num_rows, const int32_t row_size,
                      const int32_t mult, const int32_t shift, const int32_t diff_min, int8_t *out-
                      put)
```

```
void riscv_softmax_u8 (const uint8_t *input, const int32_t num_rows, const int32_t row_size,
                      const int32_t mult, const int32_t shift, const int32_t diff_min, uint8_t *out-
                      put)
```

```
void riscv_softmax_with_batch_q7 (const q7_t *vec_in, const uint16_t nb_batches, const
                                  uint16_t dim_vec, q7_t *p_out)
```

group **Softmax**

EXP(2) based softmax functions.

Functions

```
void riscv_softmax_q15 (const q15_t *vec_in, const uint16_t dim_vec, q15_t *p_out)
```

Q15 softmax function.

Here, instead of typical e based softmax, we use 2-based softmax, i.e.,:

Parameters

- [in] `vec_in`: pointer to input vector
- [in] `dim_vec`: input vector dimension
- [out] `p_out`: pointer to output vector

$$y_i = 2^{(x_i)} / \sum(2^{x_j})$$

The relative output will be different here. But mathematically, the gradient will be the same with a $\log(2)$ scaling factor.

```
void riscv_softmax_q7 (const q7_t *vec_in, const uint16_t dim_vec, q7_t *p_out)
```

Q7 softmax function.

Here, instead of typical natural logarithm e based softmax, we use 2-based softmax here, i.e.,:

Parameters

- [in] `vec_in`: pointer to input vector
- [in] `dim_vec`: input vector dimension
- [out] `p_out`: pointer to output vector

$$y_i = 2^{(x_i)} / \sum(2^{x_j})$$

The relative output will be different here. But mathematically, the gradient will be the same with a $\log(2)$ scaling factor.

```
void riscv_softmax_s8 (const int8_t *input, const int32_t num_rows, const int32_t row_size,  
                      const int32_t mult, const int32_t shift, const int32_t diff_min, int8_t  
                      *output)
```

S8 softmax function.

Note Supported framework: TensorFlow Lite micro (bit-accurate)

Parameters

- [in] `input`: Pointer to the input tensor
- [in] `num_rows`: Number of rows in the input tensor
- [in] `row_size`: Number of elements in each input row
- [in] `mult`: Input quantization multiplier
- [in] `shift`: Input quantization shift within the range [0, 31]
- [in] `diff_min`: Minimum difference with max in row. Used to check if the quantized exponential operation can be performed
- [out] `output`: Pointer to the output tensor

```
void riscv_softmax_u8 (const uint8_t *input, const int32_t num_rows, const int32_t row_size,  
                      const int32_t mult, const int32_t shift, const int32_t diff_min, uint8_t  
                      *output)
```

U8 softmax function.

Note Supported framework: TensorFlow Lite micro (bit-accurate)

Parameters

- [in] `input`: Pointer to the input tensor
- [in] `num_rows`: Number of rows in the input tensor
- [in] `row_size`: Number of elements in each input row
- [in] `mult`: Input quantization multiplier
- [in] `shift`: Input quantization shift within the range [0, 31]
- [in] `diff_min`: Minimum difference with max in row. Used to check if the quantized exponential operation can be performed
- [out] `output`: Pointer to the output tensor

```
void riscv_softmax_with_batch_q7 (const q7_t *vec_in, const uint16_t nb_batches, const  
                                  uint16_t dim_vec, q7_t *p_out)
```

Q7 softmax function with batch parameter.

Here, instead of typical natural logarithm e based softmax, we use 2-based softmax here, i.e.,:

Parameters

- [in] `vec_in`: pointer to input vector
- [in] `nb_batches`: number of batches
- [in] `dim_vec`: input vector dimension
- [out] `p_out`: pointer to output vector

$$y_i = 2^{x_i} / \sum(2^{x_j})$$

The relative output will be different here. But mathematically, the gradient will be the same with a $\log(2)$ scaling factor.

group **groupNN**

A collection of functions to perform basic operations for neural network layers. Functions with a `_s8` suffix support TensorFlow Lite framework.

4.3.2 Neural Network Data Conversion Functions

void **riscv_q7_to_q15_no_shift** (const q7_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_q7_to_q15_reordered_no_shift** (const q7_t *pSrc, q15_t *pDst, uint32_t blockSize)

void **riscv_q7_to_q15_reordered_with_offset** (const q7_t *src, q15_t *dst, uint32_t blockSize, q15_t offset)

void **riscv_q7_to_q15_with_offset** (const q7_t *src, q15_t *dst, uint32_t blockSize, q15_t offset)

void **riscv_q7_to_q7_no_shift** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)

void **riscv_q7_to_q7_reordered_no_shift** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)

group **nndata_convert**

Perform data type conversion in-between neural network operations

Functions

void **riscv_q7_to_q15_no_shift** (const q7_t *pSrc, q15_t *pDst, uint32_t blockSize)

Converts the elements of the Q7 vector to Q15 vector without left-shift.

Converts the elements of the q7 vector to q15 vector without left-shift.

The equation used for the conversion process is:

Description:

Parameters

- [in] `*pSrc`: points to the Q7 input vector
- [out] `*pDst`: points to the Q15 output vector
- [in] `blockSize`: length of the input vector

void **riscv_q7_to_q15_reordered_no_shift** (const q7_t *pSrc, q15_t *pDst, uint32_t blockSize)

Converts the elements of the Q7 vector to reordered Q15 vector without left-shift.

Converts the elements of the q7 vector to reordered q15 vector without left-shift.

This function does the q7 to q15 expansion with re-ordering

Parameters

- [in] `*pSrc`: points to the Q7 input vector

- [out] *pDst: points to the Q15 output vector
- [in] blockSize: length of the input vector

is converted into:

This looks strange but is natural considering how sign-extension is done at assembly level.

The expansion of other other operand will follow the same rule so that the end results are the same.

The tail (i.e., last (N % 4) elements) will still be in original order.

void **riscv_q7_to_q15_reordered_with_offset** (const q7_t *src, q15_t *dst, uint32_t
block_size, q15_t offset)

Converts the elements of the Q7 vector to a reordered Q15 vector with an added offset.

Converts the elements of the q7 vector to reordered q15 vector with an added offset.

Note Refer header file for details.

void **riscv_q7_to_q15_with_offset** (const q7_t *src, q15_t *dst, uint32_t block_size, q15_t
offset)

Converts the elements from a q7 vector to a q15 vector with an added offset.

The equation used for the conversion process is:

Description:

Parameters

- [in] src: pointer to the q7 input vector
- [out] dst: pointer to the q15 output vector
- [in] block_size: length of the input vector
- [in] offset: q7 offset to be added to each input vector element.

void **riscv_q7_to_q7_no_shift** (const q7_t *pSrc, q7_t *pDst, uint32_t blockSize)

Converts the elements of the Q7 vector to Q7 vector without left-shift.

The equation used for the conversion process is:

Return none.

Description:

Parameters

- [in] *pSrc: points to the Q7 input vector
- [out] *pDst: points to the Q7 output vector
- [in] blockSize: length of the input vector

void **riscv_q7_to_q7_reordered_no_shift** (const q7_t *pSrc, q7_t *pDst, uint32_t block-
Size)

Converts the elements of the Q7 vector to reordered Q7 vector without left-shift.

This function does the q7 to q7 expansion with re-ordering

Return none.

Parameters

- [in] *pSrc: points to the Q7 input vector
- [out] *pDst: points to the Q7 output vector

- [in] blockSize: length of the input vector

is converted into:

This looks strange but is natural considering how sign-extension is done at assembly level.

The expansion of other other operand will follow the same rule so that the end results are the same.

The tail (i.e., last $(N \% 4)$ elements) will still be in original order.

group **NNBasicMath**

Basic Math Functions for Neural Network Computation

Functions

void **riscv_nn_accumulate_q7_to_q15**(q15_t *dst, const q7_t *src, uint32_t block_size)
Converts the elements from a q7 vector and accumulate to a q15 vector.

The equation used for the conversion process is:

Description:

Parameters

- [in] *src: points to the q7 input vector
- [out] *dst: points to the q15 output vector
- [in] block_size: length of the input vector

void **riscv_nn_accumulate_q7_to_q7**(q7_t *dst, const q7_t *src, uint32_t block_size)
Converts the elements from a q7 vector and accumulate to a q7 vector.

The equation used for the conversion process is:

Description:

Parameters

- [in] *src: points to the q7 input vector
- [out] *dst: points to the q7 output vector
- [in] block_size: length of the input vector

void **riscv_nn_add_q7**(const q7_t *input, q31_t *output, uint32_t block_size)
Non-saturating addition of elements of a q7 vector.

2²⁴ samples can be added without saturating the result.

Description:

Parameters

- [in] *input: Pointer to the q7 input vector
- [out] *output: Pointer to the q31 output variable.
- [in] block_size: length of the input vector

The equation used for the conversion process is:

```
q7_t *riscv_nn_depthwise_conv_nt_t_padded_s8(const q7_t *lhs, const q7_t *rhs,
                                              const int32_t lhs_offset, const
                                              uint16_t num_ch, const int32_t
                                              *out_shift, const int32_t *out_mult,
                                              const int32_t out_offset, const
                                              int32_t activation_min, const int32_t
                                              activation_max, const uint16_t
                                              row_x_col, const int32_t *const
                                              output_bias, q7_t *out)
```

Depthwise convolution of transposed rhs matrix with 4 lhs matrices. To be used in padded cases where the padding is -lhs_offset(Range: int8). Dimensions are the same for lhs and rhs.

Return The function returns one of the two

- Updated output pointer if an implementation is available
- NULL if no implementation is available.

Note If number of channels is not a multiple of 4, upto 3 elements outside the boundary will be read out for the following.

- Output shift
- Output multiplier
- Output bias
- rhs

Parameters

- [in] lhs: Input left-hand side matrix
- [in] rhs: Input right-hand side matrix (transposed)
- [in] lhs_offset: LHS matrix offset(input offset). Range: -127 to 128
- [in] num_ch: Number of channels in LHS/RHS
- [in] out_shift: Per channel output shift. Length of vector is equal to number of channels
- [in] out_mult: Per channel output multiplier. Length of vector is equal to number of channels
- [in] out_offset: Offset to be added to the output values. Range: -127 to 128
- [in] activation_min: Minimum value to clamp the output to. Range: int8
- [in] activation_max: Maximum value to clamp the output to. Range: int8
- [in] row_x_col: (row_dimension * col_dimension) of LHS/RHS matrix
- [in] output_bias: Per channel output bias. Length of vector is equal to number of channels
- [in] out: Output pointer

```
q7_t *riscv_nn_depthwise_conv_nt_t_s8(const q7_t *lhs, const q7_t *rhs, const
int32_t lhs_offset, const uint16_t num_ch,
const int32_t *out_shift, const int32_t
*out_mult, const int32_t out_offset, const
int32_t activation_min, const int32_t activa-
tion_max, const uint16_t row_x_col, const
int32_t *const output_bias, q7_t *out)
```

Depthwise convolution of transposed rhs matrix with 4 lhs matrices. To be used in non-padded cases.

Dimensions are the same for lhs and rhs.

Return The function returns one of the two

- Updated output pointer if an implementation is available
- NULL if no implementation is available.

Note If number of channels is not a multiple of 4, upto 3 elements outside the boundary will be read out for the following.

- Output shift
- Output multiplier
- Output bias
- rhs

Parameters

- [in] lhs: Input left-hand side matrix
- [in] rhs: Input right-hand side matrix (transposed)
- [in] lhs_offset: LHS matrix offset(input offset). Range: -127 to 128
- [in] num_ch: Number of channels in LHS/RHS
- [in] out_shift: Per channel output shift. Length of vector is equal to number of channels.
- [in] out_mult: Per channel output multiplier. Length of vector is equal to number of channels.
- [in] out_offset: Offset to be added to the output values. Range: -127 to 128
- [in] activation_min: Minimum value to clamp the output to. Range: int8
- [in] activation_max: Maximum value to clamp the output to. Range: int8
- [in] row_x_col: (row_dimension * col_dimension) of LHS/RHS matrix
- [in] output_bias: Per channel output bias. Length of vector is equal to number of channels.
- [in] out: Output pointer

```
riscv_status riscv_nn_mat_mul_core_1x_s8 (int32_t row_elements, const int8_t *row_base,  
                                           const int8_t *col_base, int32_t *const  
                                           sum_col, int32_t *const output)
```

General Matrix-multiplication without requantization for one row & one column.

Pseudo-code `*output = 0` `sum_col = 0` for (`i = 0`; `i < row_elements`; `i++`) `*output += row_base[i] * col_base[i]` `sum_col += col_base[i]`

Return The function returns the multiply-accumulated result of the row by column.

Parameters

- [in] row_elements: number of row elements
- [in] row_base: pointer to row operand
- [in] col_base: pointer to col operand
- [out] sum_col: pointer to store sum of column elements
- [out] output: pointer to store result of multiply-accumulate

```
riscv_status riscv_nn_mat_mul_core_4x_s8 (const int32_t row_elements, const int32_t offset,
                                           const int8_t *row_base, const int8_t
                                           *col_base, int32_t *const sum_col, int32_t
                                           *const output)
```

General Matrix-multiplication without requantization for four rows and one column.

Pseudo-code `output[0] = 0 .. output[3] = 0` `sum_col = 0` for (`i = 0; i < row_elements; i++`) `output[0] += row_base[i] * col_base[i] .. output[3] += row_base[i + (row_elements * 3)] * col_base[i]` `sum_col += col_base[i]`

Return The function returns the multiply-accumulated result of the row by column

Parameters

- [in] *row_elements*: number of row elements
- [in] *offset*: offset between rows. Can be the same as *row_elements*. For e.g, in a 1x1 conv scenario with stride as 1.
- [in] *row_base*: pointer to row operand
- [in] *col_base*: pointer to col operand
- [out] *sum_col*: pointer to store sum of column elements
- [out] *output*: pointer to store result(4 int32's) of multiply-accumulate

```
riscv_status riscv_nn_mat_mult_nt_t_s8 (const q7_t *lhs, const q7_t *rhs, const q31_t
                                           *bias, q7_t *dst, const int32_t *dst_multipliers,
                                           const int32_t *dst_shifts, const int32_t lhs_rows,
                                           const int32_t rhs_rows, const int32_t rhs_cols,
                                           const int32_t lhs_offset, const int32_t dst_offset,
                                           const int32_t activation_min, const int32_t activation_max)
```

General Matrix-multiplication function with per-channel requantization. This function assumes:

- LHS input matrix NOT transposed (nt)
- RHS input matrix transposed (t)

Note This operation also performs the broadcast bias addition before the requantization

Return The function returns `RISCV_MATH_SUCCESS`

Parameters

- [in] *lhs*: Pointer to the LHS input matrix
- [in] *rhs*: Pointer to the RHS input matrix
- [in] *bias*: Pointer to the bias vector. The length of this vector is equal to the number of output columns (or RHS input rows)
- [out] *dst*: Pointer to the output matrix with “m” rows and “n” columns
- [in] *dst_multipliers*: Pointer to the multipliers vector needed for the per-channel requantization. The length of this vector is equal to the number of output columns (or RHS input rows)
- [in] *dst_shifts*: Pointer to the shifts vector needed for the per-channel requantization. The length of this vector is equal to the number of output columns (or RHS input rows)
- [in] *lhs_rows*: Number of LHS input rows
- [in] *rhs_rows*: Number of RHS input rows

- [in] `rhs_cols`: Number of LHS/RHS input columns
- [in] `lhs_offset`: Offset to be applied to the LHS input value
- [in] `dst_offset`: Offset to be applied the output result
- [in] `activation_min`: Minimum value to clamp down the output. Range : int8
- [in] `activation_max`: Maximum value to clamp up the output. Range : int8

void **riscv_nn_mult_q15** (q15_t *pSrcA, q15_t *pSrcB, q15_t *pDst, **const** uint16_t out_shift, uint32_t blockSize)

Q7 vector multiplication with variable output shifts.

q7 vector multiplication with variable output shifts

Scaling and Overflow Behavior:

The function uses saturating arithmetic. Results outside of the allowable Q15 range [0x8000 0x7FFF] will be saturated.

Parameters

- [in] *pSrcA: pointer to the first input vector
- [in] *pSrcB: pointer to the second input vector
- [out] *pDst: pointer to the output vector
- [in] out_shift: amount of right-shift for output
- [in] blockSize: number of samples in each vector

void **riscv_nn_mult_q7** (q7_t *pSrcA, q7_t *pSrcB, q7_t *pDst, **const** uint16_t out_shift, uint32_t blockSize)

Q7 vector multiplication with variable output shifts.

q7 vector multiplication with variable output shifts

Scaling and Overflow Behavior:

The function uses saturating arithmetic. Results outside of the allowable Q7 range [0x80 0x7F] will be saturated.

Parameters

- [in] *pSrcA: pointer to the first input vector
- [in] *pSrcB: pointer to the second input vector
- [out] *pDst: pointer to the output vector
- [in] out_shift: amount of right-shift for output
- [in] blockSize: number of samples in each vector

riscv_status **riscv_nn_vec_mat_mult_t_s8** (**const** q7_t *lhs, **const** q7_t *rhs, **const** q31_t *bias, q7_t *dst, **const** int32_t lhs_offset, **const** int32_t rhs_offset, **const** int32_t dst_offset, **const** int32_t dst_multiplier, **const** int32_t dst_shift, **const** int32_t rhs_cols, **const** int32_t rhs_rows, **const** int32_t activation_min, **const** int32_t activation_max)

s8 Vector by Matrix (transposed) multiplication

Return The function returns `RISCV_MATH_SUCCESS`

Parameters

- [in] lhs: Input left-hand side vector
- [in] rhs: Input right-hand side matrix (transposed)
- [in] bias: Input bias
- [out] dst: Output vector
- [in] lhs_offset: Offset to be added to the input values of the left-hand side vector. Range: -127 to 128
- [in] rhs_offset: Not used
- [in] dst_offset: Offset to be added to the output values. Range: -127 to 128
- [in] dst_multiplier: Output multiplier
- [in] dst_shift: Output shift
- [in] rhs_cols: Number of columns in the right-hand side input matrix
- [in] rhs_rows: Number of rows in the right-hand side input matrix
- [in] activation_min: Minimum value to clamp the output to. Range: int8
- [in] activation_max: Maximum value to clamp the output to. Range: int8

```
riscv_status riscv_nn_vec_mat_mult_t_svd_s8(const q7_t *lhs, const q7_t *rhs, q15_t
                                             *dst, const int32_t lhs_offset, const
                                             int32_t rhs_offset, const int32_t scatter_offset, const int32_t dst_multiplier,
                                             const int32_t dst_shift, const int32_t
                                             rhs_cols, const int32_t rhs_rows, const
                                             int32_t activation_min, const int32_t activation_max)
```

s8 Vector by Matrix (transposed) multiplication with s16 output

Return The function returns RISC_V_MATH_SUCCESS

Parameters

- [in] lhs: Input left-hand side vector
- [in] rhs: Input right-hand side matrix (transposed)
- [out] dst: Output vector
- [in] lhs_offset: Offset to be added to the input values of the left-hand side vector. Range: -127 to 128
- [in] rhs_offset: Not used
- [in] scatter_offset: Address offset for dst. First output is stored at 'dst', the second at 'dst + scatter_offset' and so on.
- [in] dst_multiplier: Output multiplier
- [in] dst_shift: Output shift
- [in] rhs_cols: Number of columns in the right-hand side input matrix
- [in] rhs_rows: Number of rows in the right-hand side input matrix
- [in] activation_min: Minimum value to clamp the output to. Range: int16

- [in] activation_max: Maximum value to clamp the output to. Range: int16

4.3.4 Convolutional Neural Network Example

group **CNNexample**

Refer riscv_nnexamples_cifar10.cpp

Description:

Demonstrates a convolutional neural network (CNN) example with the use of convolution, ReLU activation, pooling and fully-connected functions.

Model definition:

The CNN used in this example is based on CIFAR-10 example from Caffe [1]. The neural network consists of 3 convolution layers interspersed by ReLU activation and max pooling layers, followed by a fully-connected layer at the end. The input to the network is a 32x32 pixel color image, which will be classified into one of the 10 output classes. This example model implementation needs 32.3 KB to store weights, 40 KB for activations and 3.1 KB for storing the `im2col` data.

Variables Description:

- `conv1_wt`, `conv2_wt`, `conv3_wt` are convolution layer weight matrices
- `conv1_bias`, `conv2_bias`, `conv3_bias` are convolution layer bias arrays
- `ip1_wt`, `ip1_bias` point to fully-connected layer weights and biases
- `input_data` points to the input image data
- `output_data` points to the classification output
- `col_buffer` is a buffer to store the `im2col` output
- `scratch_buffer` is used to store the activation data (intermediate layer outputs)

NMSIS DSP Software Library Functions Used:

- `riscv_convolve_HWC_q7_RGB()`
- `riscv_convolve_HWC_q7_fast()`
- `riscv_relu_q7()`
- `riscv_maxpool_q7_HWC()`
- `riscv_avepool_q7_HWC()`
- `riscv_fully_connected_q7_opt()`
- `riscv_fully_connected_q7()`

[1] <https://github.com/BVLC/caffe>

4.3.5 Gated Recurrent Unit Example

group **GRUExample**

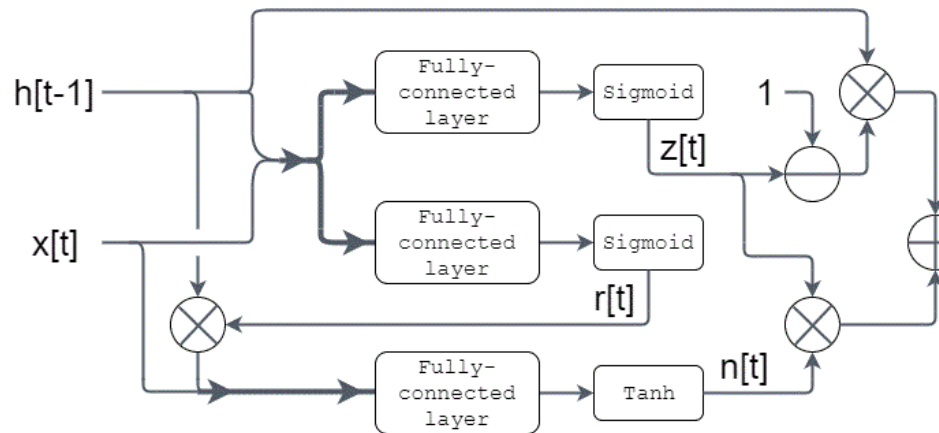

Refer `riscv_nnexamples_gru.cpp`

Description:

Demonstrates a gated recurrent unit (GRU) example with the use of fully-connected, Tanh/Sigmoid activation functions.

Model definition:

GRU is a type of recurrent neural network (RNN). It contains two sigmoid gates and one hidden state.

The computation can be summarized as:

Variables Description:

- `update_gate_weights`, `reset_gate_weights`, `hidden_state_weights` are weights corresponding to update gate (W_z), reset gate (W_r), and hidden state (W_n).
- `update_gate_bias`, `reset_gate_bias`, `hidden_state_bias` are layer bias arrays
- `test_input1`, `test_input2`, `test_history` are the inputs and initial history

The buffer is allocated as:

| reset | input | history | update | hidden_state |

In this way, the concatenation is automatically done since (reset, input) and (input, history) are physically concatenated in memory.

The ordering of the weight matrix should be adjusted accordingly.

NMSIS DSP Software Library Functions Used:

- `riscv_fully_connected_mat_q7_vec_q15_opt()`
- `riscv_nn_activations_direct_q15()`
- `riscv_mult_q15()`
- `riscv_offset_q15()`

- `riscv_sub_q15()`
- `riscv_copy_q15()`

4.4 Changelog

4.4.1 V1.0.2

This is release 1.0.2 version of NMSIS-NN library.

- Sync up to CMSIS NN library 3.0.0
- Initial support for RISC-V vector extension support

4.4.2 V1.0.1

This is release V1.0.1 version of NMSIS-DSP library.

- Both Nuclei RISC-V 32 and 64 bit cores are supported now.
- Libraries are optimized for RISC-V 32 and 64 bit DSP instructions.
- The DSP examples are now using Nuclei SDK as running environment.

4.4.3 V1.0.0

This is the first version of NMSIS-NN library.

We adapt the CMSIS-NN v1.0.0 library to use RISC-V DSP instructions, all the API names now are renamed from `arm_***` to `riscv_***`.

CHANGELOG

5.1 V1.0.2-RC1

This is the release candidate version V1.0.2-RC1 release of Nuclei MCU Software Interface Standard(NMSIS).

The following changes has been made since V1.0.1.

- **Device Templates**
 - DOWNLOAD_MODE_XXX macros are removed from riscv_encoding.h, it is now defined as enum in <Device.h>, and can be customized by soc vendor.
 - startup code now don't rely on DOWNLOAD_MODE macro, instead it now rely on a new macro called VECTOR_TABLE_REMAPPED, when VECTOR_TABLE_REMAPPED is defined, it means the vector table's lma != vma, such as vector table need to be copied from flash to ilm when boot up
 - Add **BIT**, **BITS**, **REG**, **ADDR** related macros in <Device.h>
- **NMSIS-Core**
 - Nuclei Cache CCM operation APIs are now introduced in core_feature_cache.h
- **NMSIS-DSP/NN**
 - Merged the official CMSIS 5.8.0 release, CMSIS-DSP 1.9.0, CMSIS-NN 3.0.0
 - RISC-V Vector extension and P-extension support for DSP/NN libraries are added

5.2 V1.0.1

This is the official V1.0.1 release of Nuclei MCU Software Interface Standard(NMSIS).

The following changes has been made since V1.0.1-RC1.

- **Device Templates**
 - I/D Cache enable assemble code in startup_<Device>.S are removed now
 - Cache control updates in System_<Device>.c
 - * I-Cache will be enabled if __ICACHE_PRESENT = 1 defined in <Device.h>
 - * D-Cache will be enabled if __DCACHE_PRESENT = 1 defined in <Device.h>

5.3 V1.0.1-RC1

This is release candidate version V1.0.1-RC1 of NMSIS.

- **NMSIS-Core**
 - Add RISC-V DSP 64bit intrinsic functions in `core_feature_dsp.h`
 - Add more CSR definitions in `riscv_encoding.h`
 - Update arm compatible functions for RISC-V dsp instruction cases in `core_compatible.h`
- **NMSIS-DSP**
 - Optimize RISC-V 32bit DSP library implementation
 - Add support for Nuclei RISC-V 64bit DSP SIMD instruction for DSP library
 - Add test cases used for DSP library testing, mainly for internal usage
 - Change the examples and tests to use Nuclei SDK as running environment
- **NMSIS-NN**
 - Add support for Nuclei RISC-V 64bit DSP SIMD instruction for NN library
 - Change the examples and tests to use Nuclei SDK as running environment
- **Device Templates**
 - Add `DDR_DOWNLOAD_MODE` in device templates
 - Modifications to `startup_<Device>.S` files
 - * `_premain_init` is added to replace `_init`
 - * `_postmain_fini` is added to replace `_fini`
 - If you have implemented your init or de-init functions through `_init` or `_fini`, please use `_premain_init` and `_postmain_fini` functions defined `system_<Device>.c` now

5.4 V1.0.0-beta1

Main changes in release **V1.0.0-beta1**.

- **NMSIS-Core**
 - Fix `SysTick_Reload` implementation
 - Update `ECLIC_Register_IRQ` implementation to allow `handler == NULL`
 - Fix MTH offset from 0x8 to 0xB, this will affect function of `ECLIC_GetMth` and `ECLIC_SetMth`
 - Fix wrong macro check in cache function
 - Add missing `SOC_INT_MAX` enum definition in Device template
 - In `System_<Device>.c`, `ECLIC_NLBits` set to `__ECLIC_INTCTLBITS`, which means all the bits are for level, no bits for priority

5.5 V1.0.0-beta

Main changes in release **V1.0.0-beta**.

- **NMSIS-Core**
 - Fix error typedef of CSR_MCAUSE_Type
 - Change CSR_MCACHE_CTL_DE to future value 0x00010000
 - Fix names in CSR naming, CSR_SCRATCHCSW -> CSR_MSCRATCHCSW, and CSR_SCRATCHCSWL -> CSR_MSCRATCHCSWL
 - Add macros in riscv_encoding.h: MSTATUS_FS_INITIAL, MSTATUS_FS_CLEAN, MSTATUS_FS_DIRTY
- **Documentation**
 - Fix an typo in *core_template_intexc.rst*
 - Add cross references of Nuclei ISA Spec
 - Update appendix
 - Refines tables and figures

5.6 V1.0.0-alpha.1

API changes has been maded to system timer.

- Start from Nuclei N core version 1.4, MSTOP register is renamed to MTIMECTL to provide more features
- Changes made to NMSIS/Core/core_feature_timer.h
 - MSTOP register name changed to MTIMECTL due to core spec changes
 - SysTimer_SetMstopValue renamed to SysTimer_SetControlValue
 - SysTimer_GetMstopValue renamed to SysTimer_GetControlValue
 - Add SysTimer_Start and SysTimer_Stop to start or stop system timer counter
 - SysTick_Reload function is introduced to reload system timer
 - Macro names started with SysTimer_xxx are changed, please check in the code.
- Removed unused lines of code in DSP and NN library source code which has unused macros which will not work for RISC-V cores.
- Fix some documentation issues, mainly typos and invalid cross references.

5.7 V1.0.0-alpha

This is the V1.0.0-alpha release of Nuclei MCU Software Interface Standard(NMSIS).

In this release, we have release three main compoments:

- **NMSIS-Core**: Standardized API for the Nuclei processor core and peripherals.
- **NMSIS-DSP**: DSP library collection optimized for the Nuclei Processors which has RISC-V SIMD instruction set.

- **NMSIS-NN**: Efficient neural network library developed to maximize the performance and minimize the memory footprint Nuclei Processors which has RISC-V SIMD instruction set.

We also released totally new **Nuclei-SDK**²⁴ which is an SDK implementation based on the **NMSIS-Core** for Nuclei N/NX evaluation cores running on HummingBird Evaluation Kit.

²⁴ <https://github.com/Nuclei-Software/nuclei-sdk>

GLOSSARY

API (Application Program Interface) A defined set of routines and protocols for building application software.

DSP (Digital Signal Processing) is the use of digital processing, such as by computers or more specialized digital signal processors, to perform a wide variety of signal processing operations.

ISR (Interrupt Service Routine) Also known as an interrupt handler, an ISR is a callback function whose execution is triggered by a hardware interrupt (or software interrupt instructions) and is used to handle high-priority conditions that require interrupting the current code executing on the processor.

NN (Neural Network) is a network or circuit of neurons, or in a modern sense, an artificial neural network, composed of artificial neurons or nodes.

XIP (eXecute In Place) a method of executing programs directly from long term storage rather than copying it into RAM, saving writable memory for dynamic data and not the static program code.
